Under the title "Étude sur des Médicaments Nouveaux" M. Eugène Collin, a French pharmacist, has recently published information collated from various sources, concerning several "new remedies." Amongst them was one which attracted my special attention. It was *Nigella sativa*, and I decided to make it the subject of my report because I wished to point out certain corrections that should be made in M. Collin's description and at the same time communicate to you the results of some experiments I have been making during the past few months.

* Report on Pharmacology, read before the School of Pharmacy Students' Association.

As M. Collin's article is not very lengthy I will reproduce it here (translated from the French), omitting the microscopical description and a few unimportant details.

"This plant" (*N. sativa*) "is a native of the island of Crete. It is cultivated in Egypt, Persia and India. The seeds are very commonly employed under the name of 'abesodé' or 'babe sodé' that is 'black grains.' They are also sometimes termed 'black cummin.'

"The seeds of *N. sativa* are very small, measuring $1\frac{1}{2}$ mm. in length, and $\frac{1}{2}$ mm. in their greatest breadth; they are of a dead black colour, perceptibly quadrangular, flattened longitudinally, with prominent edges. Examined with a lens the surface is seen to be finely pitted. A somewhat aromatic odour is developed when the seed is crushed, recalling the peculiar smell of umbelliferous plants.

"The seeds have been used from the earliest ages, as they are mentioned in the Bible. The Egyptians sprinkle the powdered seed on bread and cakes as a stimulant to digestion. In Hanover they are mixed with stews under the name of allspice. The inhabitants of India have used them from time immemorial as an emmenagogue. In the last century black cummin seeds have been used to stimulate the lacteal, urinary and intestinal secretions; they have also been employed as a remedy for the bites of poisonous animals, etc.

"M. Canolle has recently published the results of clinical investigations undertaken in the hospital of Karikol with black cummin seed. He has observed that after doses of 10–40 grams of the powdered seed the temperature of the body is raised, the pulse accelerated and all the secretions stimulated, especially those of the kidneys and skin; in doses of 10–20 grams they possess a well-marked emmenagogue action in dysmenorrhœa.

"Pellacani has found two alkaloids in black cummin seed which he has isolated and named respectively nigelline and connigelline.

"Nigelline resembles curarine in the physiological effects it produces on frogs and mammals, whilst connigelline more nearly approaches jaborine and atropine."

From whatever source the foregoing description of the seed is taken, it refers, without doubt, to *N. sativa*, as a comparison with a genuine sample will at once show. The three or four-sided seeds with prominent angles, flattened surfaces and peculiar odour when crushed are characteristic of *N. sativa*. The taste is something more than feebly aromatic, it is decidedly acrid.

The seeds of *N. damascena*, which are frequently substituted for *N. sativa*, develop an equally characteristic but perfectly distinct odour when crushed; their rounded shape, the deep transverse furrows, and the taste distinguish them from *N. sativa*.

That the samples of these two seeds now before you are genuine I have proved by cultivating the plants and comparing them when in flower with the descriptions and with specimens in the Kew Museum.

It is remarkable that although the two species differ so considerably, the chemical investigations carried out by Reinsch, Flückiger and Pellacani were (as I pointed out some time since in the *Pharmaceutical Journal*) made with *N. damascena*, not with *N. sativa* as published. M. Collin appends to an accurate description of *N. sativa* taken from one source, an account of the chemical constituents of *N. damascena* from another, an error which might easily have been avoided by a glance into the pharmaceutical literature of the past year or two.

The question will now naturally be asked, What seed has Dr. Canolle employed in his physiological experiments?

This I attempted to answer by a reference to Dr. Canolle's paper in the *Journal de Médecine*, of Paris. Unfortunately, I have not been able to obtain access to this journal. I have, however, consulted the works on Indian botany and Indian materia medica in our library, and found that *N. sativa* was largely cultivated there, the seed being used as a condiment and in medicine; of *N. damascena* there is no mention whatever.

To ascertain now whether the seeds described as being derived from *N. sativa* were really the seed of that plant, I repaired to the Kew Museum. Through the kindness of the Curator, Mr. Jackson, I obtained samples of specimens from Egypt, Aden, Burmah, Bombay and Madras (Karikol, where Dr. Canolle's experiments were made, being in the latter Presidency); they proved to be all true *N. sativa*, possessing the characteristic shape, odour and taste.

There can, therefore, be little doubt that the seeds administered by Dr. Canolle were those of the true *N. sativa.*

In the seed of *N. damascena* (or at least a mixture with *sativa*), Dr. Pellacani found two alkaloids, nigelline and connigelline; of the latter 35 lbs. of seed did not yield as much as half a grain; nigelline was found in larger quantity, but how much larger we are not informed. Fifteen centigrams of nigelline produced in a rabbit a flow of saliva and a discharge from the eyes which lasted about forty-five minutes, after which the animal was perfectly recovered; in its action this alkaloid resembles pilocarpine.

According to Pellacani the presence of these two alkaloids, nigelline and connigelline, satisfactorily explains the physiological effect observed by Canolle, but from what I have said it must be clear that, although these alkaloids may possibly produce effects similar to those observed by Canolle, yet of the origin of the therapeutic activity of *N. sativa* there is at present not a scrap of positive evidence.

Some years ago I examined the seed of *N. sativa*, and was fortunate in procuring a genuine sample. Details of this examination have already been published in the *Pharmaceutical Journal*, and as far as I know it is the only investigation that has ever been made of the true *N. sativa.* Although I was unsuccessful in attempting to isolate an alkaloid, I found a glucosidal principle allied to saponin, to which the name melanthin was given. This substance I have recently obtained in larger quantity and pure white in colour. *N. damascena* contains at most only traces of it.

This melanthin has never been tested physiologically, and I am afraid that at present there is but little prospect of such experiments being made, unless indeed I carry them out myself upon my own person. Saponin, however, to which melanthin is nearly related, has produced effects similar to those observed by Canolle, viz., an increase in the secretions, and even vomiting and diarrhœa; and senega, which contains a considerable amount of saponin, has been found serviceable in amenorrhœa. Until proof is adduced to the contrary it is quite within the bounds of reason to suppose that to the melanthin contained in the *N. sativa* part at least of the therapeutic activity may be due.

Being desirous of ascertaining the distribution of melanthin in the plant producing it, I had some of the genuine seed grown for me and the plants gathered at different stages of development. For the care with which this was carried out I have to thank my friend Mr. Gadd, now pharmaceutical chemist in Ramsgate, formerly a member of this Association. At the same time I had the seed of *N. damascena* grown in a similar manner.

I had eventually at my disposal plants of both species gathered—

(1) in a very young state;
(2) shortly before flowering;
(3) whilst in full flower, with unripe seed;
(4) in fruit, the seed being nearly but not quite ripe.

Unfortunately, the weather was so unfavourable in the autumn that the seed did not arrive at full maturity. The characteristic fluorescence that the crushed seeds of *N. damascena* impart to petroleum spirit or to ether was, in consequence, if present at all, entirely masked by the greenish-yellow colour of the chlorophyll. In no part of either species could this fluorescent substance be detected.

I found that all the aerial parts of *N. sativa*, at every stage of development, contained notable quantities of melanthin, especially the leaves. The roots were, on the other hand, quite free from it at all periods.

In *N. damascena* I could find no trace of melanthin in the roots at any period or in the unripe seed; the leaves and the nearly ripe seed contained traces only of either that substance or one very similar.

Should *Nigella sativa* find a place amongst pharmaceutical drugs, the dried leaves would furnish a convenient material from which pharmaceutical preparations could be made. By this means we should utilize a part of the plant which is, I believe, at present wasted, and we should avoid employing a seed rich in fixed oil, always a source of annoyance to the pharmacist. In such case we should do well to examine carefully any supply of the leaves that might be sent to us from Germany.

AMERICAN DRUGS.*

BY J. MOELLER,

Botanist and Microscopist of the Imperial Forest Institute, Mariabrunn, near Vienna.

(*Continued from page* 745.)

FOLIA ARCTOSTAPHYLI GLAUCÆ (MANZANITA).

The leaves are almost uniformly elliptical or ovate, 25 to 40 mm. long, 15 to 25 mm. wide, with a short stem, ending in a small thorn-like point. They are thick and leathery, the margins slightly thickened and entire, smooth on both sides, somewhat shiny, pale green, the primary nerve with slightly prominent secondary nerves running to the margin, similarly delicately crimped and netted on both sides. The drug is odourless and tastes

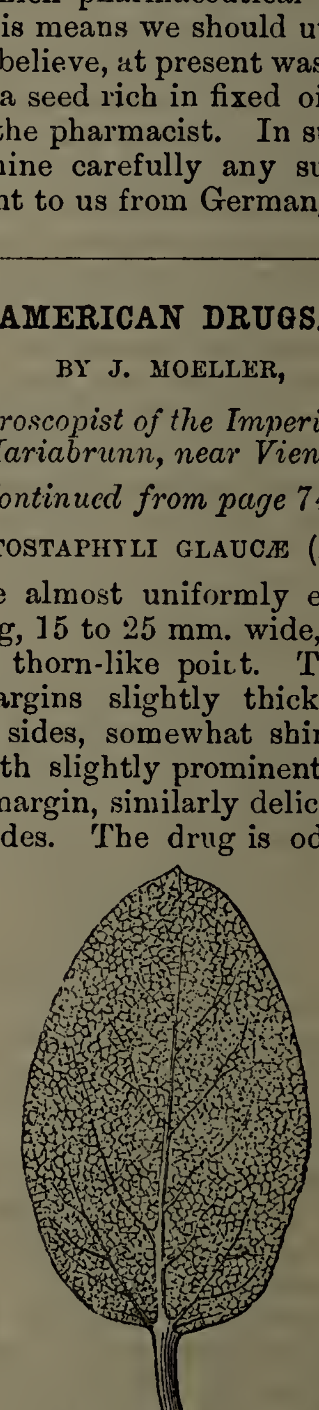

Fig. 11.—Upper side of the leaf of *Arctostaphylos glauca* (nat. size).

strong and bitter. Anatomically speaking, the leaves are interesting on account of the typically peculiar transverse arrangement of the vascular bundles. These have not the circular horizontal section, but linear and keep both sides of the leaf apart like props.

As the bast fibres do not reach the upper skin, their mechanical function is completed through layers composed of collenchymatic construction. These extend directly under the upper skin and even unite often with a structure of the neighbouring vascular collection of the same name. The leaf parenchyma contains a large quantity of tannin, which turns iron blue, but it has no specific points of secretion. I. H. Flint has found

* Reprinted from the *Therapeutic Gazette.*

"arbutin" in these leaves (*Vergl. Arch. d. Pharm.*, Bd. 218, S. 89).

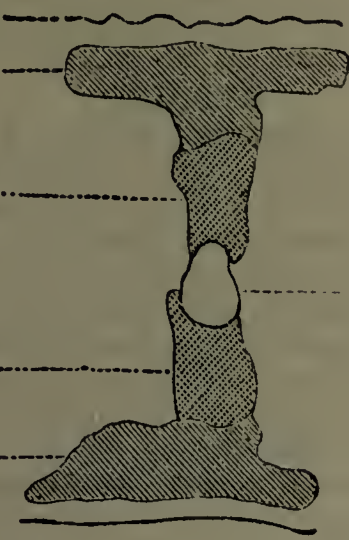

Fig. 12.—Transverse section of vascular bundles in the leaf of *Arctostaphylos glauca*:—*ee*, epidermis; *cc*, collenchyma layers; *bb*, bast bundles; *v*, central portion of the vascular bundle.

Manzanita leaves are readily distinguishable by their size and their bright colour from folia uvæ ursi, which latter have been introduced into all European pharmacies. The edge of the leaf and its nerves offer other further trustworthy earmarks by which to distinguish it. Nor is it easy to mistake it for any other kindred ericaceæ. The leaves of the *Arctostaphylos alpina*, Spr., are equal to them in size, but their edge is sharply identated, becoming fringy towards the stem. The parent plant of the manzanita leaves is the *Arctostaphylos glauca*, Lind., of California.

Ericaceæ.—This plant has long been known in California on account of its tonic and diuretic properties. It is particularly recommended in cases of catarrh of the urino-genital system, in cases of menorrhagia and incontinence of urine.

RADIX MAHONIÆ AQUIFOLIÆ.

Crooked cylindrical roots, generally from 10 to 15 mm. thick, cut for commerce into pieces, from 8 to 10 cm. long. The bark of these roots is almost 1 millimetre in thickness, of a greyish yellow colour, wrinkled lengthwise. The cylindrical pith is surrounded by layers of dense yellow wood substance. The magnifying glass enables us to detect the broad medullary rays which broaden outwards in the bark, and contrast darkly with

Fig. 13.—Section of the root of *Mahonia aquifolia*:— *b*, bark; *w*, wood.

the wood-rays, which latter are much broader and perforated by vascular pores. The bast-rays are concentrically stratified; the inner bark is homogeneous and covered with a thin dark-brown layer of a corky substance.

Microscopic Character.—The wood betrays scarcely any indication of the formation of the growth of a year. The vessels are irregularly distributed, often arranged tangentially to one another, much diversified in the lumen, but seldom exceeding 0·1 mm., with the diaphragm completely perforated, and the side walls profusely spotted and sometimes also spirally striped, and shortly scalariform (0·15 mm.). They are encased in thick-walled liber formation, woody parenchyma being scanty. All sclerotic elements are entirely absent in the young bark; the parenchyma becomes sclerotic in layers later on, giving the bark the appearance of being formed in layers of bast fibres, of which fibres the secondary bark is in reality totally free. The fibres of the parenchyma are remarkably short, often inseparably blended together into whetstone-shaped bundles, and seldom more than three-jointed. The primary medullary rays are ten to fifteen-rowed to begin with, and widen towards the exterior, reaching a width of 1 mm. and even more. As the plant grows older a secondary medullary ray can be found between each pair of bark-rays, which also acquire a respectable width as they proceed outward. The middle groups of cells of the medullary rays become sclerotic in bundles without changing the size and shape of the cells. The middle bark is composed of thin-walled, much elongated parenchyma cells, closely pressed together, and covered by a delicate layer of cork.

The parenchyma is filled with a yellow substance easily removed by washing, whilst the membranes of the sclerotic elements of the bark and wood are very intimately impregnated by the same, Bœdeker did not succeed in producing nitrate of berberin by his microchemic reaction. These roots furnish but faint traces of oxalate of lime, or of any crystals, although a proper treatment with sulphuric acid will generally produce a few gypsum needles. Starch is entirely absent, from which we are led to conclude that it is gathered in the summer season.

Mahonia Aquifolia, DC. (*Berberis Aquifolium*, Pursh.) —Berberideæ.—The parent plant of this drug is that very generally cultivated ornamental evergreen with pointed needle-like leaves (indigenous to North America, but also found wild in some parts of Europe), so closely allied to varieties of barberry. The plant is said to be distinguished from this and all other varieties of *Berberis* by the alkaloids which it contains, and to which it owes its medicinal properties. This alkaloid was discovered at the Michigan College of Medicine, by Professor Jungk, and represented as a yellow, amorphic substance, possessing an alkaline reaction, and having a strong bitter taste. The salt produced by it is white, notwithstanding the yellow colour of its base.

It is not yet known whether or not this alkaloid (called "mahonine," after the discoverer of the plant) is identical with the xanthopicrit (= berberine) obtained by Chevallier and Pelletan from xanthoxylum. It is well known that berberine is obtained from a series of plants differing considerably among themselves. This drug was first used in cases of syphilis some three years ago and is now much used and highly esteemed, especially in America. It is less effective in the first stages than after a preceding mercurial treatment. Extract of berberis, like iodide of potassium, seems to be a powerful adjunct to mercury, eliminating the latter from the system, together with the materies morbi. According to the American view, the beneficial results reached by this line of treatment are unquestionable, whatever may be thought of the theory as such. The preparation has also been successfully applied in all uninflamed chronic affections of the skin, and in chronic or subacute catarrh of the vagina and uterus, especially in those cases of endometritis which are marked by a secretion of albumen. There are a fluid and a solid extract known to commerce, 20 to 30 drops of the former, 3 to 6 grains of the latter, being the proper dose.

(*To be continued.*)

IN THE KAURI GUM FIELDS.*

Sombre, solemn, and grand are the kauri forests of Northern New Zealand. If you want beauty of mixed foliage, of wide-spreading, branching trees, all interlaced with knotted vines and tufts of rosy blossoms—forests where the golden sunlight steals in delicately-divided rays through the exquisite canopy of tall tree-ferns, to fall in radiant gleams on the carpet of all manner of silver-backed and other lovely ground-ferns—you will find these in perfection wherever the grievously "improving" hand of the settler has spared the primeval bush. Alas, that we should have to say, such precious visions of Eden are already few and far between—only to be found in the least frequented districts.

But the kauri forests are a thing altogether apart; and alas! indeed, of these also we must say that they are rapidly diminishing before the too busy axe of the lumberer. The kauri is the pine-tree of New Zealand, the sole representative of the coniferous family, and a very noble representative it is, though by no means answering to our ordinary notions of pine-trees, inasmuch as its foliage consists of leaves instead of needles; but it is tall and straight as a mast, and a very majestic mast, for these stately trees range from fifteen to fifty feet in girth, and attain a height of from a hundred to two hundred feet ere they commence throwing out the branches which form their crown of sombre green. This is a special industry peculiar to Northern New Zealand, and the precious gum is a semi-fossilized deposit which is found buried at a depth of five or six feet below the surface of the ground, on tracts of open land, where in bygone ages grew kauri forests which have long since disappeared. It is thought probable that these forests have been burnt, and that the exceeding heat liquefied the resin and caused it to flow more freely, for the digger is sometimes rewarded by finding a lump as big as his own body, though more frequently it lies buried in fragments from the size of an egg to that of a man's head.

The value of the gum varies with its colour, which is sometimes of a rich brown, sometimes bright amber, and occasionally almost like pale crystal. Sometimes it is clouded, sometimes quite clear, revealing flies and tiny beetles which, perhaps for ages, have been enshrined in its transparent depths. The clearest and most crystalline pieces fetch the highest prices, and are carved into ornaments hardly to be distinguished from amber, but very much more brittle. When these extra fine pieces have been selected, the rest is sold in the Auckland market at from £30 to £40 a ton, and is purchased by English and American manufacturers of varnish. The amount collected must be enormous, as the value of the annual export from the colony ranges from £70,000 to £200,000. None is found in the Southern Isle, nor, indeed, to the south of latitude of 37° 30′, which is the southernmost limit of the growth of the kauri.

Whether the special qualities of the buried gum are due to old age, or to the possible action of fire, is unknown; but that which is obtained from the living tree is altogether worthless for the market, being soft and sticky,—in fact, simple resin. Large quantities in this condition are sometimes found about the roots of growing trees in the forest: but of this very little can be turned to account.

At one time as many as two thousand men made their living as professional gum-diggers, but in these more settled days other occupations are found to be more remunerative, and a comparatively small number now adopt this as their regular employment,—those who do so being for the most part the unsettled, roving members of the community. They are a mixed lot,—of very much the same stamp as an average colony of gold-diggers. Bohemians of every nation, European, American, Australian, all find their way to the gum-fields. There men of all classes rub shoulders; and a white-handed "swell" lately, perhaps, an over-extravagant officer in Her Majesty's service or an unworthy member of one of the universities, may deem himself fortunate should he chance to fall in with some sturdy navvy who will accept him as his pal.

KEPHIR.*

BY PROFESSOR H. STRUVE.

Kephir is a beverage which is prepared by a peculiar process of fermentation from the milk of cows and other animals. It has been in use from time immemorial by the inhabitants of the northern declivities of the high Caucasian mountain range, to whom it possesses the same importance as koumis does to the nomades of the south-eastern steppes of Russia. The last-named beverage was for the first time brought to the notice of the scientific world in 1784, and since then it has been frequently the subject of investigations, but only within a few decades has it attained greater importance as a remedy.

On the other hand, kephir was, even in Russia, totally unknown until two years ago, although in 1867 Dr. Sipowitsh had made a short communication on this subject to the Caucasian Medical Society, which remained buried in the archives of the latter. Ten years later, in 1877, Dr. Shublowski published a more detailed paper on kephir which, however, failed to direct the attention of science or that of the public towards this new beverage; the proper impulse was first given from Moscow in 1881, almost a century after the first notice of koumis.

On December 1, 1881, Ed. Kern read a paper before the Imperial Society of Naturalists at Moscow (*Bull. Soc. Impér. des Natur. de Moscou*, 1881, p. 141) on "Kephir, a new milk ferment from the Caucasus," which he had collected during his travels. The requisite investigations had been made by Ed. Kern under the supervision and in the laboratory of Professor Goroshaukin. The result is that, within the last two years, kephir was not only introduced as a medicine from the southern to the northern section of Russia; but that also a number of papers and pamphlets on this subject has been published. During the latter part of the past year kephir has also been noticed in other countries, among others by Professor Dr. F. Cohn, at the meeting held December 13, by the section for Natural Sciences of the Silesian Society at Breslau. Kephir has already become an article of speculation, is procurable in commerce, and will doubtless be further scientifically investigated. The narrow circle in which for centuries kephir has been harboured with almost religious piety, has been broken, and it has become public property, notwithstanding the method of its preparation is still surrounded with a certain mystery, depending upon the so-called kephir-grains, the new milk ferment of Kern. This can only be procured from the mountain tribes; but after it has been obtained, kephir may be prepared with the requisite precautions, at all times, in winter or in summer.

This present mystery concerning the origin and nature of the kephir-ferment invites further investigations, and it will doubtless not be a long time before the preparation of kephir in all its details will have been ranged with the known phenomena of fermentation in general. Then, most likely, this simple beverage and remedy of the mountain tribes of the high Caucasus will be accorded an important position among the domestic and general remedies, more particularly as towards koumis. But years of observation will be required to determine its true value; at present kephir is beginning to become a fashionable remedy.

The author has undertaken the chemical investigation of kephir with the view of applying to it the results of his protracted investigations of milk, and of determining the changes produced by this ferment; although more difficult and complicated than expected, he hopes in the near future to be able to report his results.

Tiflis, January 30, 1884.

PHARMACY LAW IN ONTARIO.

AFTER experiencing failure in two previous attempts to obtain an amendment in the law regulating the practice of pharmacy and the sale of poisons in the province of Ontario that was passed in 1871, the pharmacists of that division of the Dominion of Canada have this session succeeded in securing their object. The course which legislation has taken on this occasion, though perhaps not a common one, is certainly conducive to simplicity, for instead of patching up the old Act with a series of amendments, it has been absolutely repealed and its provisions re-enacted with such modifications as experience has shown to be desirable. The provisions of the Act of 1871 may be found in the first volume of the present series of this Journal, and in accordance with what is now our usual practice in respect to colonial Pharmacy Acts, the text of the Act which supersedes it will be printed in a future number for permanent reference; but it may be convenient that we should here briefly summarize the new law and indicate the most important changes that have been effected, especially as some of them are in the direction contemplated in this country for the amendment of the Pharmacy Act, 1868.

In the first place provision is made for the continuance of the Ontario College of Pharmacy, which is reinvested with the duties of supervising the examinations and registration, and with authority to grant certificates of competency. It may be mentioned that membership of this College is involved in registration, and that every person registered under the Act becomes *de facto* a member, is entitled to call himself a pharmaceutical chemist, and has to pay for the uses of the College a yearly subscription of four dollars. In addition the new Act provides that a further sum of four dollars annually shall be paid on account of every branch establishment, and requires that all *employés* or assistants who manage or have charge of such additional places of business shall be legally qualified pharmaceutical chemists. Power has also been given to the Council to raise the fee for the qualifying examination from four to ten dollars. Only registered pharmaceutical chemists are legally authorized to compound prescriptions of legally authorized medical practitioners, or to keep an open shop for retailing, dispensing, or compounding poisons enumerated in a schedule, or to assume or use the title of "chemist and druggist," or "chemist," or "druggist," or "pharmacist," or "apothecary," or "dispensing chemist" or "druggist," in any part of the province of Ontario. As to the persons entitled to registration, it was provided in the Act of 1871 that this privilege should extend, without examination, to persons in business on their own account before the passing of the Act; or who had before that time served an apprenticeship of three years and acted as an assistant for one year. Under the new law this privilege is continued to such persons, upon payment of a fee of ten dollars, during another twelve months, after which it is to cease. Further, persons approved of by the Council of the College, who hold diplomas from the Pharmaceutical Society of Great Britain or certificates from any pharmaceutical college in the Dominion of Canada or elsewhere, may also be registered without examination. Any other person, before being eligible for registration, must pass an examination, for which hitherto there has been no requirement as to previous practical training. But henceforth a candidate will have to satisfy the Council that he has served as an apprentice to a regularly qualified pharmaceutical chemist for a term of three years, whilst any apprenticeship commenced subsequently to the passing of the present Act will have to be evidenced by a contract in writing, and the term of the apprenticeship will not be deemed to commence for the purposes of the Act until proof has been furnished to the Council that a suitable preliminary examination has been passed. Upon any person being registered under the Act he will be entitled to receive from the Ontario College of Pharmacy a certificate authorizing him to carry on business for a specified time, which, if carrying on business on his own account, he is to display in a conspicuous position in his shop; but no person who is in default in respect to the annual fee payable to the College will be entitled to exercise the privileges of a pharmaceutical chemist. In the event of the death of a person in business, his business may be carried on by an executor, administrator or trustee, if and so long as it is conducted by a qualified pharmaceutical chemist and the annual registration fee of four dollars continues to be paid. An important alteration has been made in the provision as to the penalty for offences under the Act, which is now definitely fixed at "twenty dollars and costs," instead of, as before, "not exceeding twenty dollars." This will probably help to curb the lenient propensities of magistrates which result sometimes in practically fining the prosecutor instead of the offender.

The provisions as to the sale of poisons are, in the main, similar to those in our own Pharmacy Act, save that there is no exemption in favour of patent medicines. Potassium cyanide does not appear in the first part of the poison schedule, but this part includes Indian hemp, digitalin and cedar oil. In the second part neither essential oil of almonds nor red or white precipitate occur, but it contains several substances not included in the British schedule,—carbolic acid, calabar beans, St. Ignatius' beans, pink root, podophyllin, ether, iodine, potassium iodide and potassium bromide. Paregoric is specially excluded from the opium preparations subject to the regulations. One subject of controversy during the passage of the Bill through the legislature seems to have been the arsenical insecticides, such as "Paris green" and "London purple," which are now so extensively used by agriculturists in North America. It was contended that it would be against the public interest and convenience that the supply of these substances should become a monopoly in the hands of chemists and druggists, and, eventually, this view of the case prevailed, for it is provided that nothing in the Act shall prevent the sale by persons not registered of the arsenical insecticides, so long as they are sold in well-secured packages, distinctly labelled with the name and address of the seller and marked "poison," and a record of each sale is kept by the seller. The Committee charged with the conduct of the Bill appear to have pressed very strongly the argument that druggists are alone qualified to sell such poisonous compounds, but to little avail; it was found that some compromise on this point was the price that would have to be paid for the new law, and the regulation as to labelling was the result. The question is not unlike one that was recently argued in this country, and may come up again before long. It is, therefore, of interest to note the spirit in which this settlement has been accepted by the Ontario chemists. The *Canadian Pharmaceutical Journal* says:—"By this arrangement a right has been conceded which was so questionable as not to bear assertion, and was practically inoperative. Druggists will continue to sell as great a proportion of these insecticides as ever they did, and from the restrictions surrounding their sale by other dealers will no doubt in the end secure the great bulk of the trade." In conclusion, there is a provision that all compounds named in the British Pharmacopœia shall be prepared according to the formulæ directed in the latest published edition of that work, "unless the College of Physicians and Surgeons of this province select another standard," or unless the label distinctly shows that the compound is prepared according to another formula.

BOTANICAL LECTURES AND PRACTICAL DEMONSTRATIONS AT THE GARDENS OF THE ROYAL BOTANIC SOCIETY OF LONDON.

It will be noticed, by reference to the advertisement of the School of Pharmacy of Great Britain in the present number of this Journal, that Professor Bentley will commence his course of lectures and demonstrations on "Systematic and Practical Botany," at the Gardens of the Royal Botanic Society, in Regent's Park, on Saturday morning next, May 3, at eight o'clock. The lectures will be continued on the succeeding Friday and Saturday mornings, at the same hour until the end of July.

We have been favoured with a copy of the Calendar of the Pharmaceutical Society of Ireland for 1884, and regret to observe from the "Statistics" that although the number of pharmaceutical chemists on the Register, as compared with the previous year, has increased from 219 to 234, the number of Members of the Society has again decreased, from 81 to 71.

* * *

From the Annual Report of the Pharmacy Board for Victoria it appears that during the year 1883 ten persons presented themselves for the "major" examination (there is no "minor") of whom nine passed. A candidate to be eligible for this examination must previously have served as an apprentice for not less than four years, attended one course of lectures, passed examinations in the University of Melbourne, or some school or college recognized by the Board, in the subjects of materia medica, medical botany and practical chemistry, and passed an examination in practical pharmacy before the Board. The same number went up for the "modified" examination, open to persons who have served three years' apprenticeship to a chemist and druggist, of which term three months had been completed at the time of the passing of the Act, and of them seven passed. The candidates for the "preliminary" examination, which is compulsory before the commencement of an apprenticeship, numbered 44, and 21 passed. It is stated that of the total number of persons registered under the Victoria Pharmacy Act in the four years 1880–83, inclusive, 14 passed the "major" and 41 the "modified" examination of Victoria; 29 were registered under certificates from the Pharmaceutical Society of Great Britain, and one under a certificate from the Pharmaceutical Society of Ireland; five qualified by foreign diplomas, and 42 were registered as having been in business in the colony before the passing of the Act.

* * *

We willingly call attention to the report upon another page of the formation at Manchester of a Pharmacy Students' Association "for the promotion of intercourse amongst chemists' assistants, apprentices and others in any way connected with pharmacy, and the discussion of subjects tending to the welfare of all interested in pharmacy." It will be seen that the young Association has adopted the plan of appointing "Reporters" to keep the members acquainted with what is being done in botany, chemistry, materia medica and pharmacy, which constitutes one of the best means of providing a good supply of useful information for those who attend the meetings.

* * *

From a recently issued Report of the Commissioners of Customs it appears that during the year ending March 31, 1883, the gross amount of duty collected upon chloral hydrate (3*s.* per lb.) imported into the United Kingdom amounted to £965, being a decrease of £39 as compared with the previous year. Chloroform yielded during the same time a revenue of £11 (14*s.* per gallon); sulphuric ether, £17 (25*s.* per gallon); iodide of ethyl, £1 (13*s.* per gallon); and collodion, £2 (24*s.* per gallon). Besides these sums, £167 was collected on transparent soap in the manufacture of which spirit had been used (3*d.* per lb.), showing a falling off of £98.

* * *

The Report on the Progress and Condition of the Royal Gardens at Kew during 1882, the preparation of which was unusually delayed in consequence of the pressure of official duties, shows that in the course of that year the visitors amounted to 1,244,167, a number enormously larger than that recorded in any previous year, and nearly half as many again as in 1881. On Whit Monday more visitors (95,300) entered the gardens than had ever before been admitted in a single day. It is gratifying to find that notwithstanding the unprecedented number of visitors in 1882, and the absolute freedom with which every part of the establishment is made accessible, the Director is able to report that the amount of damage which the collections suffered may be described as practically *nil.*

* * *

We notice that among the topics treated of in the Report is that of the cinchona nomenclature, and there is a decided expression of opinion in favour of Dr. Trimen's conclusions. Some interesting information is also given respecting the cultivation of jalap in Jamaica, and several other similar subjects.

* * *

As a consequence of the proposal referred to last week, as having been put forward in Massachusetts, to make the United States Dispensatory the authoritative standard as to the quality of drugs, a remonstrance, signed by the President and all the living ex-Presidents of the Massachusetts Medical Society, has been presented to the Senate and House of Representatives, urging that "the United States Pharmacopœia should be the only standard for the preparation and sale of drugs and medicines," and protesting against any present alteration of the Adulteration Act in force in the State.

* * *

According to the *Weekly Drugs News* four separate robberies have been effected in Denver by a man, whose method of operating was first to rouse a pharmacist after business hours and then to present a loaded revolver instead of a prescription. It is satisfactory to learn that the largest haul made by the miscreant only amounted to fifty dollars and a box of cigars; but probably this loss will be sufficient to engender caution in the local pharmacists who may in future be summoned by the night bell.

* * *

It is reported that a patent has been taken out in Germany for an electric process of preparing metallic aluminium, by which it will be possible to produce it at about one-fourth of the present cost.

* * *

At the next meeting of the Chemical Society, to be held on Thursday, May 1, a paper will be read on "Benzoylactic Acid and some of its Derivatives" (Part I.), by W. H. Perkin, jun., Ph.D., and one on "Fluorene," by W. R. E. Hodgkinson.

* * *

The last meeting of the session of the Manchester Pharmaceutical Association will be held at the Owens College (Medical Theatre, Oxford Road entrance), on Tuesday evening next, April 29, at 7·30 p.m., when a paper will be read on "Coal: The Products of its Distillation and the Manufacture of Coal Gas" (illustrated with experiments and the oxhydrogen lantern), by A. W. Duncan, F.C.S., and F. C. J. Bird.

* * *

A meeting of the School of Pharmacy Students' Association will be held an Thursday, May 1, at 8 p.m., when a paper on "Blood" will be read by Mr. Charles Shapley, and a Report on Materia Medica will be made by Mr. W. Elborne.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held on Wednesday, April 23, 1884, the report of the College of Preceptors on the examination held on April 8th was received.

Three hundred and seventy-five candidates had presented themselves for examination, of whom *two hundred* had failed. The following *one hundred and seventy-five* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

Annis, Ernest George ....Leicester.
Appleby, Geo. Henry Vane ...Sunderland.
Appleton, Arthur ....Driffield.
Armitage, George..................York.
Arrandale, James William......Denton.
Askew, Frederic ....Workington.
Aspinall, Hortensius ....Liverpool.
Bailey, Willis ....Eastry.
Balmford, John Thomas........ Longwood.
Barden, Tedbar.....................Dewsbury.
Bartholomew, Edwin Robert ...Ludlow.
Barrett, Edith ....Daventry.
Barrett, William Louis .... Portsmouth.
Beattie, James B...................Fife.
Beck, John Frederick ....Honiton.
Blakemore, John Bowen.........Oakengates.
Blayney, William H. .... Haslingden.
Blissett, Francis Homan ....Bristol.
Brett, George ....Louth.
Brookes, John Humphrey ......Chesterfield.
Burgess, Llewellyn Ernest ......Aberavon.
Burnett, George ....Great Broughton.
Butterfield, Thomas A. C. ......Keighley.
Carpenter, Albert Hemsley ...London.
Carron, Herbert Burgess ......Leyton.
Caunt, John William ....Derby.
Clark, James........................Thornhill.
Collins, Joseph ....Catterick.
Cook, Harry ....Barrow-in-Furness.
Cooke, Charles Fowler............Sileby.
Cooper, Frederick William......Brightlingsea.
Corfe, Robert ....Maidstone.
Croft, Duterau ....Middleham.
Crosdale, Robert Morgan ......Oldham.
Cross, Edward Robert............Scarborough.
Dalziel, Charles Michie ....Aberdeen.
Darlington, Thomas...............Haslington.
Davies, John Albert ....Aberystwith.
Dewey, Thomas Henry ....Merton.
Draper, Arthur Longfellow......Brigg.
Durno, Alexander Emslie ......Aberdeen.
Edwards, Edward..................Brecon.
Edwards, Edward..................Cardiff.
Edwards, Walter ....London.
Emett, Thomas.....................Fulwood.
Enness, Walter Frederick ......London.
Ettles, Wm. James McCulloch.Elgin.
Evans, Alfred Philip ....London.
Evans, Francis Richard A........West Bromwich.
Ferguson, Thomas ....Stirling.
Ford, Frederick Charles ....Kilsby.
Freeman, John......................Tetbury.
Gartside, Charles ....Oldham.
Gelling, John Alexander.........Douglas.
Gifford, James ....Blackburn.
Gilderdale, Frederick ....Wakefield.
Goodwin, James ....Nuneaton.
Gourlay, John ....Montrose.
Greenhalgh, Thomas Earnest ...Blackpool.
Greenwood, William Russell ...Howden.
Gross, Walter Henry ....Northampton.

Hall, Robert ....Market Rasen.
Halmshaw, William................Brigg.
Harbottle, Bernard ....Alnwick.
Harding, Charles Thomas ....London.
Harries, Benjamin ....Llandilo.
Harrison, Arthur Neville ....Dowlais.
Harwood, Thomas William ...Driffield.
Haynes, Edward Thomas ....Oxford.
Hearne, William Gustavus.......Redhill.
Hedley, Charles Richard..........Newcastle-on-Tyne.
Herrington, Edmund William..Reading.
Hill, Malcolm ....Glasgow.
Hodder, George William..........Frome.
Holgate, Herbert......................Catterick.
Hounam, Christopher ....Langholm.
Hutchin, Llewellyn Albert Jas.Saffron Walden.
Hutton, Frank Danks...............Dunfermline.
Jenkins, William ....St. Dogmaels.
Jones, Hugh Kyffin..................Mochdre.
Jones, Lewis............................Aberdovey.
Jones, Thomas John ....Holyhead.
Jones, William.........................Aberystwith.
Kenderdine, Alfred George ...Stafford.
Kent, Thomas Oliver ....Wye.
Kent, Wm. Hy. Plaisted ....East Molesey.
Kidd, Walter John ....Halifax.
Kinnear, James Arthur ....Dundee.
Kirkby, Thomas Henry ....Marshchapel.
Langford, Frederick Charles ...London.
Leech, Charles Richard ....Cambridge.
Lloyd, Benjamin Caradoc ....Flint.
Lloyd, Richard Edward ....Garston.
London, Walter Augustus ....Redditch.
Longstaff, William Edwin ....Silloth.
McCardell, James......................Glasgow.
McIntyre, Francis Gibb ....Glasgow.
McKerrow, William James ...Aberdeen.
McLaren, Frederic Donald.......Beverley.
Maggs, Arthur Samuel ....St. Leonards on Sea.
Marshall, Rupert Henry..........Walsall.
Matthews, Henry Gilbert ....London.
Mawer, William Fred..............Grimsby.
May, James ....Musselburgh.
Middleton, Richard Watson ...Ilkley.
Millar, James Herd..................Edinburgh.
Miller, Richard ....Preston.
Minet, Alfred ....London.
Mingay, Adolphus Alfred ....Burton-on-Trent.
Mitchell, John Albert..............Bradford.
Nettleton, George William.......Brighouse.
Nidd, John Henry ....Boston.
Northwood, Herbert Wm. W...Arundel.
Ogilvie, James Hay..................Aberdeen.
Oliphant, Edward ....Grange.
Ord, Bertram Thomas.............Gateshead.
Ough, Lewis............................Plymouth.
Owen, Griffith Charles ....Carmarthen.
Palmer, George William...........Ely.
Palmer, James ....Oxford.
Pearson, Ernest ....Cromford.
Perrett, Frederick James ....Weston-Super-Mare.
Peterkin, Charles John ....Elgin.
Phillips, Thomas ....St. Clears.
Pinckney, Charles Edward.......Peterborough.
Pole, William ....Shetland.
Ramsden, Thomas Prince ....Pontefract.
Rideal, Frank ....Hyde.
Robertson, Alexander ....Elgin.
Robertson, Thomas Cannon ...Oban.
Robin, Hugh Millar ....Perth.
Roe, George ....London.
Rugg, Walter James ....London.
Scorgie, John ....Ellon.
Scott, William Robert.............Galashiels.
Scowby, Joseph Newsome ....Sheffield.
Shillcock, Sydney.....................Bromley, Kent.
Silversides, Richd. B. Garbutt Darlington.
Sim, David ....Dundee.
Smith, Edward Charles ....London.
Smith, Harry George .... Downham Market.
Smith, Robert ....Forres.
Southall, Harold William ....Birmingham.
Southall, John Edmund ....Birmingham.
Stansfield, John Mills ....Birkdale.
Stewart, Hawthorn ....Ayr.
Streatfield, Edward Henry.......Maidstone.
Stubbins, Henry ....Brigg.
Sturton, Charles Hubert..........London.
Taylor, Richard Noble.............Barrow-in-Furness.
Tharratt, George ....Louth.
Thomas, Owen Edward ....Bangor.
Thomson, Robert Greig ....Buckhaven.
Tupholme, John James ....Spilsby.
Turpin, Ernest ....London.
Tweedie, Thomas Shortridge ...Annan.
Vincent, William ....Truro.
Vinden, Frederick William.......London.
Voisin, Ernest Osmond B. ....Jersey.
Walker, James ....Aberdeen.
Walker, William Henry ....Willenhall.
Wansbrough, Edwin George L.. Barrow-in-Furness.
Ward, Oswald Thomas ....Diss.
Watson, William Henry..........Spennymoor.
Webster, Thomas Findlater ...London.
Werner, Emil Alphonse ....Dublin.
Wheeldon, Edwin.....................Warrington.
Wight, William ....Alnwick.
Willoughby, Samuel Walton ...Plymouth.
Wilson, John Henry ....Coventry.
Wilson, John Woolhouse ....London.
Woodruff, Thomas ....Stalybridge.
Woodward, William ....London.
Young, Edward Francis ....Portishead.
Young, George Herbert ....Brigg

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	14	9	5	Jersey	2	1	1
Birmingham	17	8	9	Lancaster	6	5	1
Brighton	4	1	3	Leeds	17	9	8
Bristol	9	5	4	Lincoln	11	6	5
Cambridge	7	5	2	Liverpool	15	5	10
Canterbury	4	2	2	London	54	30	24
Cardiff	12	4	8	Manchester	24	9	15
Carlisle	7	4	3	Newcastle-on-T.	9	5	4
Carmarthen	13	6	7	Northampton	3	1	2
Carnarvon	10	4	6	Norwich	7	1	6
Darlington	8	4	4	Nottingham	12	4	8
Douglas	3	1	2	Oxford	2	2	0
Dundee	8	5	3	Peterborough	3	1	2
Edinburgh	26	6	20	Sheffield	6	2	4
Exeter	8	2	6	Shrewsbury	5	3	2
Glasgow	17	7	10	Southampton	4	1	3
Guernsey	1	0	1	Truro	2	2	0
Hull	12	9	3	Worcester	2	0	2
Inverness	5	3	2	York	6	3	3

The questions set for examination were as follows:—

LATIN.

(*Time allowed—from* 11 *a.m. to* 12.30 *p.m.*)

I. Translate into English either A (Cæsar) or B. (Virgil).

The Candidate must not attempt both.

A. CÆSAR.

(i.) Ita ancipiti proelio diu atque acriter pugnatum est Diutius quum nostrorum impetus sustinere non possent alteri se, ut coeperant, in montem *receperunt;* alteri ad impedimenta et carros suos se *contulerunt.* Nam hoc toto proelio, quum ab hora septima ad vesperum pugnatum sit, aversum hostem videre nemo potuit. Ad multam noctem etiam ad impedimenta pugnatum est, propterea quod pro vallo carros objecerant, et e loco superiore in nostros venientes tela *conjiciebant,* et nonnulli inter carros rotasque, mataras ac tragulas subjiciebant nostrosqui vulnerabant.

(ii.) Hoc proelio trans Rhenum nuntiato, Suevi, qui ad ripas Rheni *venerant,* domum reverti *coeperunt;* quos Ubii, qui proximi Rhenum incolunt, perterritos insecuti, magnum ex his numerum *occiderunt.* Caesar, una aestate duobus maximis bellis confectis, maturius paulo, quam tempus anni postulabat, in hiberna in Sequanos exercitum deduxit: hibernis Labienum praeposuit; ipse in citeriorem Galliam ad conventus agendos profectus est.

II. Grammatical Questions.

(*For those Candidates who take Cæsar*)

1. Give the principal parts of the verbs in italics.
2. Decline *impetus, impedimenta, aestate,* and *maximis bellis.*
3. Give the three degrees of comparison of all the adjectives in the above extracts.
4. What is the difference between *in montem* and *in monte?*
5. What do you know of *Labienus?* Who were the *Suevi* and *Sequani?*

B. VIRGIL.

I. Translate into English :—

(i.) Aeole (namque tibi divum pater atque hominum rex
Et *mulcere dedit* fluctus, et *tollere* vento),
Gens inimica mihi Tyrrhenum navigat aequor;
Ilium in Italiam portans, victosque Penates:
Incute vim ventis, submersasque obrue puppes,
Aut *age* diversos, et *disjice* corpora ponto.
Sunt mihi bis septem praestanti corpore nymphae,
Quarum, quae forma pulcherrima Deïopeiam
Connubio jungam stabili, propriamaque dicabo.

(ii.) At domus interior regali splendida luxu
Instruitur, mediisque parant convivia tectis.
Arte laboratae vestes, ostroque superbo;
Ingens argentum mensis, caelataque in auro
Fortia facta patrum, series longissima rerum,
Per tot ducta viros antiqua ab origine gentis.

II. Grammatical Questions.

(*For those Candidates who take Virgil.*)

1. Give the principal parts of the verbs in italics.
2. Decline throughout *vis, rerum, domus* and *praestanti corpore.*
3. Give the three degrees of comparison of all the adjectives in extract (ii.)
4. Give the case and construction of *tibi, vento, ventis, Deïopeiam propriam* (extract i.)
5. Who was *Aeolus?* Where was *Tyrrhenum aequor?* and what were *Penates?*

(*For all Candidates*).

III. Translate into Latin :—

1. This life of ours is short, but that one is immortal. 2. We often walked in the garden in order that we might refresh ourselves. 3. The generals were punished because they had not buried the bodies. 4. I wish to learn where the camp of the enemy is. 5. We must pray that all things may be well.

ARITHMETIC.

(*Time allowed—from* 12.30 *p.m. to* 2 *p.m.*)

1. A gentleman, whose average expenditure is £3. 4*s.* 9½*d.* per week, saves every calendar month £15. 7*s.*; find his annual income.

2. Reduce to its simplest form

$$\frac{5\frac{5}{6}}{7\frac{7}{8}} \text{ o } 3 \times \frac{1-\frac{1}{10}}{7\frac{7}{8}-5\frac{5}{6}}$$

3. Divide 9·614 by ·0000019; and $\frac{2\frac{1}{5}}{5\frac{1}{2}}$ by $\cdot 00\dot{3}$.

4. Reduce 11 cwt. 19 lbs. to the decimal of 10 tons 1 cwt. 6 lbs.

5. If 1 decalitre of wheat makes 6 kilog. 68 decag. of bread, how much wheat will be required to make 59 myriag. 1 kilog. 788 gr. of bread of the same quality?

6. Twenty navvies can dig a trench 160 metres long, 2 m. broad, and 1 m. 2 decim. deep, in 8 days; in how many days will twenty-four navvies dig a similar trench 90 m. long, 1 m. 80 centim. broad, and 1 m. 6 decim. deep?

7. How many pieces (12 yards each) of paper, 1 ft. 9 in. wide, would be required for a room measuring 37 ft. 7 in. by 27 ft. 9 in. and 13 ft. 6 in. high; and what will it cost at 7½*d.* a yard.

ENGLISH.

(*Time allowed—from* 3 *p.m to* 4.30 *p.m.*)

1. Enumerate the personal pronouns, simple and compound.

2. Give illustrations of the use of the verbs *set* and *sit*; and mention any similar pairs, with their past tenses and past participles.

3. Analyse the following sentence:—

"No surly porter stands, in guilty state,
To spurn imploring famine from the gate."

4. Parse fully the following sentence:—

"O yes, I have felt a proud emotion swell,
That I was British born."

5. Punctuate the following passage, and, where necessary, put in capital letters:—at any rate i made up my mind to be so dreadfully industrious that i would leave myself not a moment's leisure to be low-spirited for i naturally said esther you to be low-spirited you and it really was time to say so for i yes i really did see myself in the glass almost crying as if you had anything to make you unhappy instead of everything to make you happy you ungrateful heart said i.

6. Write briefly the life of some eminent English statesman or soldier (*one* only) of the present century, *or* give a short outline of recent events in the Soudan.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was delivered at the rooms of the above Association on Wednesday evening, April 9, by Mr. G. M. Winter, on "Benzine Derivatives." Mr. J. J. Edwards presided.

The lecturer, having explained the nature of hydrocarbons and carbohydrates, said it was with the former class of bodies he was about to deal; he briefly demonstrated the chemistry of the paraffin, olefine, and acetyline series. Passing to the benzine series he explained the manufacture, chemistry, and properties of benzine and toluine. In the second part of the lecture he dealt with the chemistry of the alcohols and amines. The lecture, which was illustrated with numerous diagrams, was listened to with marked attention, and at the conclusion a hearty vote of thanks was accorded to the lecturer.

LIVERPOOL REGISTERED CHEMISTS' TRADE ASSOCIATION.

The ninth annual meeting of the Registered Chemists' Trade Association of Liverpool was held at the Royal Institution, Colquitt Street, on Thursday, April 3, 1884, the President, Dr. C. Symes, in the chair.

The following Annual Report of the Committee was presented as follows:—

"In placing before the members of the Association a *résumé* of the proceedings during the ninth year of its existence, the Committee have to remark that various important matters affecting the general interests of the trade have arisen, to which they have given careful attention. Intimation was received towards the close of last session of Parliament that the Medical Acts Amendment Bill would be brought before the House, and that it was desirable a clause should be inserted giving pharmacists a position upon the Pharmacopœia Committee. Immediate action was taken in the matter, resulting in a petition—to which two hundred and fifty signatures were attached in favour of such clauses—being sent to the senior member, Mr. Whitley, for presentation to Parliament. Letters pointing out the advantage of having on the Committee those who possessed a practical knowledge of this work were also written to Lord C. J. Hamilton and Mr. S. Smith, asking their favourable consideration of the proposed amendments, from whom replies promising support were received. Owing to the press of business this Bill was postponed until the present session; it is now passing through Committee and further action may be necessary. That the Members of Parliament should be more fully informed of our requirements, the Secretary was requested to obtain and forward to them Professor Attfield's addresses, delivered at Southampton and Southport. This has been done, and copies have been sent to the representatives of Liverpool, Western Division of Lancashire and Birkenhead. Attention having been directed in the recent poisoning case to the sale of fly papers containing arsenic, it was thought desirable in the interests of the trade to issue a circular cautioning chemists against the sale of such papers. The Benevolent Fund of the Pharmaceutical Society having strong claims upon us collectively as well as individually, a donation of £2 2*s*. has been forwarded by the Treasurer from the funds of our Association. The annual supper took place on November 15, 1883, accompanied with excellent music and recitations. It was considered one of the most successful of the series. Continued demand for 'The Liverpool Price List' has necessitated a re-issue. The sixth edition is now in the hands of the printer, and will be ready for sale during the present month. The Committee are pleased to report an increased number of members, showing that the steady and progressive work of the Association is being appreciated. The Treasurer's statement of accounts, duly audited, shows a balance of £19 9*s*. 2*d*., exclusive of £2 7*s*. 6*d*. due for Price Lists, in favour of the Association."

The Treasurer's financial statement, duly audited, having also been read, it was proposed by Mr. J. Woodcock, seconded by Mr. Turner, and carried,—"That the report and financial statement be adopted, and that the Secretary be instructed to have them printed and a copy sent to every chemist in Liverpool, Birkenhead and neighbourhood."

Mr. J. Woodcock proposed, Mr. J. J. Smith seconded, the election of Dr. Symes as President, which was carried unanimously.

The retiring members of the Committee, Messrs. Ellithorne, Hocken, Parkinson, A. Redford, Turner, and Warhurst, were re-elected, and Mr. G. Alexander was elected to fill the place of Mr. W. Parry.

Votes of thanks to the officers for their services in the past year having been passed, the proceedings terminated.

MANCHESTER PHARMACY STUDENTS' ASSOCIATION.

A meeting of chemists' assistants and apprentices took place at the Young Men's Christian Association, Peter Street, Manchester, on Tuesday, March 11, to consider the advisability of forming an association for the benefit of the junior pharmacists and apprentices of the city and suburbs. The unanimous opinion being that such an association was desirable, the business of drawing up rules and electing officers was immediately proceeded with, it being also resolved to ask Mr. A. H. Jackson, B.Sc., to accept the presidency of the Association.

At a subsequent meeting, held (by permission of the Council) in the Materia Medica Museum, Owens College, Mr. Alfred H. Jackson was elected President.

The following form the Committee for the ensuing year:—

President, A. H. Jackson, B.Sc.; Vice-Presidents, W. Elborne, A. W. Duncan; Honorary Treasurer, J. W. Hughes; Committee, F. A. Astley, C. H. Griffiths, J. E. Milford, A. B. Rhodes; Reporters, W. Kirkby (Botany), A. W. Duncan, F.C.S. (Chemistry), W. Elborne (Materia Medica), F. C. J. Bird (Pharmacy); Honorary Secretary, F. C. J. Bird, 8, Herbert Street, Cheetham.

NOTTINGHAM CHEMISTS' ASSOCIATION.

The Pharmaceutical Chemistry Class of the above Association, which has been under the able tuition of Professor Clowes, D.Sc., F.I.C., having just concluded a most successful term at the University College, the students were put through a practical and written examination, occupying two evenings, by their teacher.

The following are the names of those who have been successful:—

Prize and Certificate	1st. Mr. John F. Liverseege.
Certificates	2nd. Mr. James Stanley.
	3rd. Mr. Geo. W. Harris.
	4th. Mr. Edwin Roe.
	5th. Mr. Chas. J. Fryer.
	6th. Mr. F. C. Hemming.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, April 17. Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—Messrs. W. Alabaster and E. L. C. Muspratt.

During the evening a ballot was held, and the following gentlemen were declared by the Scrutators, Dr. Miller and Mr. Louis, duly elected Fellows of the Society:—Messrs. J. P. Battershall, W. D. Borland, J. C. Bose, W. D. Crumbie, A. F. Dimmock, H. G. Greenish, W. J. Grey, J. Gaskell, J. W. Pratt, A. G. Perkin, W. H. Perkin, jun., and G. H. Wainwright.

Dr. Percy F. Frankland then read a paper—

On the Influence of Incombustible Diluents on the Illuminating Power of Ethylene.—The present communication forms a sequel to a paper read by the author "On the Illuminating Power of Ethylene when Burnt with Combustible Non-Luminous Diluents" (*Chem. Soc. Journ.*, Jan., 1884). In all cases the gases were consumed from a Referee's burner. Great care was taken to ensure the purity of the ethylene and the diluents (carbonic anhydride, nitrogen, oxygen and atmospheric air) employed. The author records his observations in a series of tables and curves. He sums up the principal results as follows:—Mixtures of ethylene, with the incombustible diluents, carbonic anhydride, nitrogen, aqueous vapour and atmospheric air, possess a lower illuminating power than pure ethylene. In all mixtures of ethylene with either carbonic anhydride, nitrogen or aqueous vapour, the intrinsic luminosity of the ethylene is reduced. In mixtures of ethylene with atmospheric air the intrinsic luminosity of the ethylene remains unimpaired until the air forms about 50 per cent. of the mixture. Mixtures of ethylene with oxygen in insufficient quantity to form an explosive mixture, possess a greater illuminating power than pure ethylene, the intrinsic luminosity of the ethylene being greatly increased. The disilluminating effects of carbonic anhydride, nitrogen and water vapour are due partly to dilution and partly to refrigeration, *i.e.*, the cooling occasioned by the introduction of inert gas into the flame. This refrigeration is proportional to the specific heats of the gases, but in the case of carbonic anhydride and aqueous vapour, it is augmented by the absorption of heat, which takes place in the dissociation of the aqueous vapour, and in the reduction of the carbonic anhydride to carbonic oxide. Of the four diluents, carbonic anhydride, nitrogen, aqueous vapour, atmospheric air, the first is the most and the last is the least prejudicial to the illuminating power; nitrogen and atmospheric air, however, become more equalized in their effects, as the proportion in which they are present increases, complete disillumination of the ethylene being effected by the same proportion of each.

Mr. Cross then communicated a paper—

On Trichloropyrogallol. By C. S. S. WEBSTER.—Messrs. Cross and Bevan found that by the action of chlorine upon lignose and bastose chlorinated derivatives were obtained, similar in properties and composition to the derivatives obtained by the action of chlorine upon various astringent substances of natural origin; but while the latter are made up for the most part of compounds which are aromatic in the strict sense of the word, the former contain no compounds of this order, but are converted into such under the action of chlorine. These authors also found that the amorphous chlorinated derivative from bastose had certain features of resemblance to the mairogallol of Stenhouse and Groves. The author of the present paper was therefore induced to reinvestigate the formation of this mairogallol. He finds that the reaction by which it is formed is divisible into two stages, which can be separated. In the first a trichloropyrogallol is formed, and it is this compound which subsequently undergoes condensation to the C_{18} derivative in question. This body, $C_6Cl_3(HO)_3 3H_2O$, was prepared as follows:—To 5 grams of pyrogallol 12 c.c. of strong acetic acid are added, the mixture is kept cool and a rapid current of dry chlorine is passed through; in about half an hour the new compound separates as a semi-solid mass of fine needles. The reactions of this body are almost identical with those of tribromopyrogallol, giving a deep blue coloration with baryta water, etc. The author has also prepared mairogallol, leucogallol, xanthogallol and tribromopyrogallol, and confirms the statements of Stenhouse and Groves in almost every particular. He has, however, improved the yield of these substances by slightly modifying the original processes.

The Secretary then read the following papers:—

The Synthesis of Galena by Means of Thiocarbamide. By J. EMERSON REYNOLDS.—Some time since the author noticed that when sulphur urea was heated with an alkaline solution of lead hydrate the lead sulphide was thrown down in a specular layer. In the present paper he gives the best method of obtaining this specular coating on glass, brass, etc. Two solutions are used; one contains 90 grams of sodium hydrate and 75 grams of lead tartrate in a litre of water, the other contains 17 grams of sulphur urea in a litre. Equal volumes of the two solutions are mixed and heated in a clean beaker; at about 50°, a specular layer, which is at first silvery and translucent, forms on the vessel; it thickens as the temperature rises and becomes opaque, resembling a brilliant face of a crystal of native galena. The excess of the sulphide separates out after boiling a short time as a very dense easily washed precipitate having the appearance of very finely powdered galena. The author hopes to be able to utilize this separation for analytical purposes. The coating adheres with considerable tenacity to glass, brass, etc., and when the patent rights which control the production of ammonium sulphocyanide lapse this galena plating may be advantageously applied to many useful purposes. Two glass vases, one coated externally, the other internally, and a piece of brass tube plated with galena were exhibited.

Dr. Armstrong said that the author gave no proof that this coating really consisted of galena, *i.e.*, crystallized lead sulphide.

On the Analysis of Woodall Spa. By W. T. WRIGHT.—Woodall lies about midway between Lincoln and Boston. In 1811 a boring was made for coal which was abandoned at 277 yards owing to the rising of a spring. This spring has since acquired some reputation as a medicinal remedy for gout, rheumatism, etc. Its properties are apparently due to the bromine and iodine which it contains. The spring was analysed by Dr. Frankland in 1875. The author gives a very complete analysis of the water. It contains 11113·73 parts per million of chlorine, 49·7 of bromine, and 5·21 of iodine. The spring is much richer in iodine and bromine than any other in this country. The author also gives a short account of the geological structure of the district.

On the Critical Temperature of Heptane. By T. E. THORPE and A. W. RÜCKER.—In a previous paper one of the authors carefully determined the superficial tension of heptane, which was in c. g. s. units at 0° 22·19. From this number the critical point of heptane was calculated to be 281°. Pawleski has shown that a constant difference exists between the critical temperature and boiling points of strictly homologous compounds. This difference is in the case of hexane 182·3°. Normal heptane boils at 98·4° which, added to the constant 182·3°, gives 280·7° as the critical point of heptane.

The Society then adjourned to May 1.

Parliamentary and Law Proceedings.

PROSECUTION UNDER THE 17TH SECTION OF THE PHARMACY ACT.

At the Peterborough Petty Sessions, on Wednesday, April 9, before C. J. Sturge, Esq. (Chairman), and Messrs. Whitwell and English, Henry Bellamy, licensed hawker, Padholme Road, Peterborough, was charged with having unlawfully sold, on March 25 last, at the parish of Werrington, to Alfred Wright, Assistant Secretary to the Chemists and Druggists' Trade Association of Great Britain, a certain poison, to wit, laudanum (the same being a preparation of opium), and not labelled with the name and address of the seller of the same, in contravention of the Pharmacy Act, 1868.

Mr. Henry Glaisyer, Solicitor to the Association, Birmingham, conducted the prosecution, and Mr. J. A. Percival, Peterborough, appeared for the defence.

Mr. Glaisyer, in opening the case, explained that there was a large amount of illegal trading being carried on, and that in the interest of the public as well as the trade the Association was doing its utmost to suppress this breaking of the law. He went on to state that defendant travelled about the country selling drugs, and that on the day in question Mr. Alfred Wright visited Werrington, a village about four miles from Peterborough, where he met defendant with his van, which was fitted up as a chemist's shop, hawking drugs from house to house. He (Mr. Wright) purchased, amongst other articles, some laudanum, which was a preparation of opium, and came within the Act relating to poisons. It might be contended that the defendant was employed by a properly qualified chemist, but he called the attention of the Bench to the fact that it was the seller, *i.e.*, the one who regulated and controlled the sales, who was liable. In this case such a person was Bellamy.

Mr. Alfred Wright said he was Assistant-Secretary to the Association, and resided in Birmingham. On the 25th of March last he went to the village of Werrington, about four miles from Peterborough, and purchased from the defendant, who was travelling with a van fitted up as a chemist's shop, half an ounce of laudanum. The bottl was labelled—"Laudanum—'Poison'—Arthur Carlton, Dispensing Chemist, 18, Long Causeway, Peterborough." He had analysed the poison in question, and found it to be a preparation of opium. The name of the defendant was on the van, and it was he who personally supplied him with the poison.

The Chairman: If it had been sold at Mr. Carlton's shop it would have been all right?

Witness: Yes.

In cross-examination witness stated that the name of A. Carlton, Chemist and Druggist, Peterborough, also apppeared upon the van.

Mr. J. A. Percival, for the defence, contended that the sale by defendant was on the same level as any sale by an apprentice or any other person in Mr. Carlton's legitimate employment, and that there was nothing in the Act which enforced defendant to sell in the shop only and not outside.

Mr. Arthur Carlton said defendant was in his own employment and travelled for him, but was not a qualified chemist. The articles sold were labelled with his (witness's) name and address, and the drugs were made up in his shop.

In cross-examination by Mr. Glaisyer, witness said Bellamy had complete control of the business conducted by him, and received from him (witness) a fixed salary and commission on sales. Bellamy was not a qualified chemist and druggist.

Re-examined by Mr. Percival: Bellamy had been in witness's employment since 1882, and was previously a chemists' porter. He had also been three years in a surgery and four years with a chemist.

Mr. Glaisyer, in addressing the Bench, quoted in detail the case of Templeman *v.* Trafford, after which, at the request of the magistrates, handed them the report of the trial. He also called their attention to the fact that even if Mr. Carlton was the seller the Act required that the buyer and seller should be introduced to each other, which was impossible when the poison was being hawked four miles off.

The Bench retired to consider their decision, and, on returning into Court, the Chairman said that they had given the case careful consideration, because it was a very fine point. Following, however, the case of Templeman *v.* Trafford in the Law Courts Reports, they held that the defendant was the seller of the poisons. The Act was framed to protect people buying them, and, if a man went four miles away from the shop, strictly he was the seller under the Act and he must be convicted. At the same time he did not believe defendant intended breaking the law. The penalty would be the minimum of 6*s.*

Mr. Glaisyer applied for the costs of the Trade Association's witness.

Mr. Carlton said it was usual for the Association to pay their witnesses.

The Chairman: Is that so?

Mr. Glaisyer answered that it was sometimes so.

Mr. Carlton: It should certainly be so in this case, especially as I am one of the members of the Society.

The ordinary Court costs only were added to the penalty.

Review.

MEDICAL GUIDE TO CONTREXÉVILLE. (VOSGES). By Dr. DEBOUT D'ESTRÉES, Médecin Inspecteur des Eaux. J. and A. Churchill. London.

This little book, which is dedicated to Doctor Garrod, is a translation of the author's French manual adapted to English readers. Contrexéville is a village which once formed part of the kingdom of Lorraine, and which now belongs to the department des Vosges, and to the district of Mirecourt. The soil is essentially calcareous; and it contains certain mineral springs which it is the object of the writer to bring prominently into notice and to introduce to the British public.

More than a century ago the place was visited by patients suffering from gravel and diseases of the bladder; and also by those afflicted with gout and disorders of the liver.

Of late great improvements have been effected; a bath establishment has been erected; a "pavilion" has been built; and the visitor in search of health will find all the accessories which are so liberally provided in similar continental resorts.

There are six springs which have been carefully *captured* (that is rendered available for treatment), of which the chief one, the Source de Pavillon, is under Government protection. A spring called la Souveraine does not seem to be in favour, its recomendation being free access to the fountain and the low price of the bottled water. Analysis determines the springs to be of a calcareous alkaline nature, of moderate strength, lithium being present; whilst iron with a trace of arsenic appears in the sediment of the *sources* specially recommended. The Source du Prince has long enjoyed a local reputation in chronic affections of the eye.

Owing to their chemical composition the use of the waters of Contrexéville is clearly indicated for gout. Alkalines (says Professor Charcot), and above all lithium, administered in small well diluted doses, have a remarkable effect on gout. They delay the paroxysms; they sometimes dissolve and reduce the deposits already formed and give more flexibility to the joints. Such results are claimed by Dr. D'Estrées for his favourite springs, and the diluted manner in which the alkaline salts are exhibited is advanced as the explanation of their success when the stronger waters of Carlsbad or Vichy have failed.

Reasoning from the teachings of analysis he proceeds to show their beneficial action in cases of gravel, stone, vesical catarrh, diseases of the prostate, infantile incontinence of urine, and hepatic colic; and he extends their application to the treatment of diabetes. Poor Madame de Sévigné, when she went to Vichy, was bled and purged on her arrival, and began the first day of her cure by swallowing twelve glasses of the water from the spring of the Grande Grille. Such heroic practices have disappeared from Vichy and elsewhere; thirty glasses are no longer taken in a day, and in this anæmic age a little more blood in the system is rather wanted than its abstraction.

It is a subject of regret to Dr. D'Estrées that the late Emperor Napoleon III. did not carry out his intention in 1866 of visiting these healing springs.

Of Contrexéville it has been said by another writer, that it is the annual rendezvous of the cleverest men, the wittiest talkers, and the most noted *gourmets* that one common malady can assemble. Its therapeutic advantages are warmly advocated in this Guide, which is free from that style of direct advertisement too common in publications of this nature.

Obituary.

Notice has been received of the death of the following:—

On the 24th of February, Mr. Richard Clay, Chemist and Druggist, Market Place, Cromford. Aged 70 years.

On the 25th of February, Mr. Hugh Cowan, Chemist and Druggist, High Street, Thurso. Aged 69 years.

On the 26th of February, Mr. William Cartwright, Chemist and Druggist, Hessle Road, Hull. Aged 44 years.

On the 7th of March, Mr. John Copeland, Chemist and Druggist, Cleveland, Somerset. Aged 56 years.

On the 7th of March, Mr. Joshua Laverty, Chemist and Druggist, New North Road, London. Aged 34 years.

On the 8th of March, Mr. Thomas Parnell, Chemist and Druggist, Oakham. Aged 60 years.

On the 16th of March, Mr. John Tily, Chemist and Druggist, Sevenoaks. Aged 68 years.

On the 21st of March, Mr. Robert Falconer, Chemist and Druggist, Nairn. Aged 60 years.

On the 21st of March, Mr. Fawcett Bowerbanks, Chemist and Druggist, Market Street, Cockermouth. Aged 58 years.

On the 21st of March, Mr. Walter Charles Bucknoll, Chemist and Druggist, Malden Road, Kentish Town. Aged 69 years.

On the 24th of March, Mr. Frank William Steel, Pharmaceutical Chemist, Fish Street Hill, London. Aged 37 years.

On the 24th of March, Mr. James Wood, Chemist and Druggist, Stonehaven, Kincardineshire. Aged 65 years.

On the 29th of March, Mr. William Frederick Blake, Pharmaceutical Chemist, High Street, Stroud, Gloucestershire. Aged 65 years. Mr. Blake had been a Member of the Pharmaceutical Society since 1856, and for many years held the office of Local Secretary.

On the 4th of April, Mr. Samuel Hunt, Chemist and Druggist, Market Hill, Sudbury. Aged 41 years. Mr. Hunt had been a Member of the Pharmaceutical Society since 1871.

On the 5th of April, Mr. Benjamin Johnson, Chemist and Druggist, Arkwright Street, Nottingham. Aged 45 years.

On the 7th of April, Mr. William Martin, Chemist and Druggist, Market Harborough. Aged 42 years. Mr. Martin had been a Member of the Pharmaceutical Society since 1869.

Standard Galenical Preparations.

Sir,—The paper on "Extract of Nux Vomica," by Mr. Schacht, which is printed in your last issue, seeks to maintain certain opinions that call for some reply from me. First, let me thank Mr. Schacht for the manner in which he has expressed his dissent from certain propositions that I have advanced, and let me hope that in the remarks I am about to make there may be found that same spirit of courteous criticism which pervades all that Mr. Schacht has said on the other side.

The main point in the paper referred to resides in the apparently decided opinion that Mr. Schacht holds upon the general question of standard galenical preparations, the official recognition of which I have advocated, and in the special case of nux vomica Mr. Short and I have proved the feasibility of producing. We have defined a standard preparation of nux vomica as a preparation that "contains a definite and constant quantity of total alkaloid." The first objection supposed by Mr. Schacht to obtain against the adoption of this definition is stated in the following words:—"There is no doubt that a large portion of the medical activity of the drug does depend upon the alkaloids it contains, but I am acquainted with no proof that all the rest is inert." This sentence will pass very well for a paraphrase of a passage in the paper upon "Tincture of Nux Vomica," which I contributed, in conjunction with Mr. Short, to the Southport meeting of the Pharmaceutical Conference:—"It will be at once conceded that the important feature in a typical tincture of nux vomica is, or should be, uniformity in alkaloidal strength: the other constituents, though doubtless valuable, are of secondary importance." That is to say, the other constituents, principally fixed oil and fat, are not potent poisons, an increase in the dose of which to the extent of a grain or two would lead to fatal results. The next objection Mr. Schacht raises is that "if we are to standardize at all, we should standardize each potential element by itself and not a mixture of elements, one of which is of undetermined power." Theoretically this will be at once admitted, but, practically, I ask who has yet determined the quantitative relation of strychnine to brucine that is therapeutically the most active? We know that strychnine is a most potent toxic agent; the exact physiological action of brucine we are as yet unacquainted with, but we do know that, as an alkaloid, it is much less toxic than strychnine is. Having in view the production of a preparation of nux vomica that shall be, as far as possible and feasible, constant in therapeutic action, two courses are open to us. First, to make the proportion of the strychnine alone constant, and, second, to make the proportion of total alkaloid constant. The first course, besides being at the present time impracticable, would lead us to disregard the physiological activity of brucine, including its possible effect upon the action of strychnine. The alternative remains and strongly recommends itself, namely, to render the entire quantity of alkaloidal constituents constant and definite. Mr. Schacht urges against this, that the proportion of strychnine to brucine in the total alkaloid is naturally subject to variation, and he exhibits a table of results, under the impression that they lend support to this objection. But I would point out to Mr. Schacht that the table which he reproduces from a paper on "Extract of Nux Vomica," by Mr. Short and myself, is a table of analyses showing the proportion of strychnine and brucine in commercial extracts of nux vomica, no two of which have probably been prepared by precisely the same process. In fact, I have since learnt that in reference to four of them this is actually the case, and in one instance an entirely different solvent was used for extracting the nux vomica. To prove the statement that the proportion of strychnine to brucine in nux vomica is inconstant, a statement which at present we can neither affirm nor deny, it is necessary to make a series of analyses of the original seeds, which has not yet been done, but I hope soon will be by Mr. Short and myself. Even when this has been settled it will no doubt still be considered for many reasons preferable to make the standard "total alkaloid." I regret to notice from Mr. Schacht's concluding passages in reference to the "15 per cent. standard" that he yet fails to see the point of my remarks which were made in reply to the self-same objections at the Evening Meeting of the Pharmaceutical Society in February last, but as these have been fully reported in your Journal of February 9, I shall not reiterate them now. I would only remark that since this time the processes which Mr. Short and I have proposed for the preparation of standard galenical preparations of nux vomica have been tried by many pharmacists, both wholesale and retail, and have been found to be practicable and successful on the small and large scale. "If a sample comes out below the standard" it must assuredly be rejected for medical use; but such a result could only ensue when the details of the process were not faithfully adhered to. So far I have heard no valid objections to the official recognition of standard galenical preparations, while the position of the question has been greatly strengthened by the adhesion, among others, of so eminent a scientific pharmacist as Professor Redwood, who has not only advocated, but also devised a process for the preparation of a standard liquid extract of cinchona.

The production of standard galenical preparations of potent drugs, which, in the majority of cases, needs the expenditure of a vast amount of preliminary scientific work, marks out a distinct line of progress and research in the pharmacy of the future—I mean, I think so.

WYNDHAM R. DUNSTAN.

ESTIMATION OF TOTAL ALKALOIDS IN EXTRACT OF NUX VOMICA.

Sir,—Mr. G. F. Schacht, in a paper published last week, describes a modification of Dragendorff's indirect process for estimating a mixture of strychnia and brucia.

Mr. Schacht prepares a volumetric test solution of potassio-mercuric iodide of such a strength that (to quote his own words) "each c.c. of this solution precipitates 0·00184 gram of mixed strychnia and brucia."

There are no details given in illustration as to how this constant factor (0·00184) is obtained in operating on a solution containing a mixture of strychnia and brucia in unknown proportions. Perhaps Mr. Schacht will record the details, as his process (if found reliable) appears more convenient than the quantitative method of Messrs. Dunstan and Short.

A careful manipulator, able to work out an algebraic simultaneous simple equation, should find no great difficulty in Dragendorff's process as detailed in his 'Plant Analysis,' the chief source of error being the rather uncertain composition of the precipitate.

8, *Torrington Place, W.C.* GEORGE SMITH.

SPIRIT OF NITROUS ETHER.

Sir,—Some months since, in commenting upon the proceedings of the Pharmaceutical Conference, you mentioned (referring to a paper of mine) the "interminable subject of sweet spirit of nitre."

Upon opening the Journal for April 12, and seeing two prominent articles upon this subject, I naturally thought that now, at least, the question was to be finally settled. Perhaps it was my own fault, due to too great expectation induced by the source of these papers, that I was disappointed, but such, I am sorry to say, was the case.

Of the first paper, viz., the one by Mr. MacEwan, I have only two remarks to make; the first is that the figures given under the head of "Diminution of Separation Volume" seem very instructive, because, if correct (which I have no reason to doubt), they show that the details of the manufacture are of the utmost importance.

During winter, Mr. MacEwan has found a greater loss of "ethereal liquid" in two months than was sustained by the samples shown by me in Southport in seven months, chiefly summer.

Moreover, these samples, now nearly fourteen months old, I find to separate nothing appreciable less than they did then.

They have, however, not been unstoppered since that time as far as I am aware. The second point is Mr. MacEwan's method of estimating the acidity, which I believe to be incapable of accurate results, as decinormal soda solution immediately decomposes sweet spirit of nitre; indeed, any alkali does so more or less rapidly.

Mr. Dott states that I consider aldehyde to be the active ingredient, and this I must most positively contradict. I said that I considered we had as much right to impute the activity to aldehyde as to nitrous ether, and gave my reasons for believing that Mr. Rimmington's argument in favour of the notion that nitrous ether produced the effects noticed, would apply with equal, if not greater, force to aldehyde. I never, however, stated or believed that aldehyde was the active principle, although I do now believe the activity is probably due to some polymeric form of aldehyde, such as paraldehyde or some nitro compound of it.

Mr. Dott's comparison between the action of aldehyde forming acetic acid in the blood, and vinegar in the stomach,—rather a stretch,—is unfortunate in the face of the fact that acetic acid or combinations containing it (such as oxymel simplex, oxymel scillæ, etc.) are constantly used in similar cases as sp. æth. nit., and not unfrequently in conjunction with it. Christison gives, amongst other actions of actic acid, the following:—stimulant, diaphoretic, and diuretic.

The same actions are imputed by the same author to sp. æther. nit., with the single addition of antispasmodic.

The medical authority quoted by Mr. Dott does not seem to have investigated the subject himself, and his views are similar to those taught forty years ago, and more or less accepted since, for the simple reason that no better theory has been advanced. The best proof, however, of their not being true is the fact that the sp. ætheris nitrosi of the Edinburgh Pharmacopœia, which, no doubt, contained, to say the least, a much larger proportion of the nitrous ether than any other, has not remained in demand and was, indeed, recommended by Christison forty years ago in the same dose as now employed with the present article.

That a nitro compound such as nitro-glycerine should decompose into a nitrite (and something else) in the blood is not surprising; but, I would ask, is diuresis the most marked result of the action of nitro-glycerine in the system?

I am very sorry that Mr. Dott has not been more successful with the hydric sulphide process, which is the only one which has yet occurred to me as likely to estimate the nitrous ether and nothing else; but he perhaps gave it up because it did not "go as it ought," or in other words, the spirit did not contain what it was expected to do.

With regard to the process finally adopted by Mr. Dott for the estimation of nitrous ether, he will find that I suggested at Southport (*Ph. J.*, Nov. 17, 1883, p. 392) practically the same thing; but I omitted the acid as unnecessary, because the preparation contains something (not aldehyde, as that is not present in sufficient quantity) which so decomposes as to render the acid unnecessary.

This something, which Mr. Dott entirely ignores but which I believe to be more probably the chief ingredient wanted, is consequently so far estimated at the same time, by my method. I may say that at Southport I stated that the test I had suggested was only a comparative one, as with different proportions of water different results would be obtained, but that with the same quantities the results were constant. This remark was not in the paper and was not reported.

I have only, in conclusion, to hope that this subject may remain "interminable" until some satisfactory conclusion has been arrived at.

Liverpool. A. C. ABRAHAM.

PHARMACY AT THE ANTIPODES.

Sir,—As your correspondent "Inquirens" solicits information as to the prospects of pharmacists at the Antipodes, I will briefly lay before your readers my experience on the subject, gained during a travel which I took nearly two years ago through Victoria, New South Wales, Tasmania, and New Zealand.

Businesses in the large towns are conducted in much the same style as in England, and from what I was informed are rather more remunerative than here. Higher prices are charged for nearly all things, but expenses are heavier as drugs, chemicals, sundries, etc., have to be imported. There is a fair amount of trade to be done in the up-country townships, but it is of a mixed character and would require some previous special experience.

I should certainly advise any young pharmacist intending to settle in Australia or New Zealand to take an assistantship first and acquire a knowledge of the special requirements of the trade. I was informed that situations are easily obtainable by pharmacists possessing the Minor or Major qualification, and that the remuneration is very good.

173, *Marylebone Road, N.W.* A. P. LUFF.

F. T.—The term "patent medicine" is commonly applied to preparations that are liable to pay stamp duty, although they may not be the subject of a patent. The selling of such articles necessitates the taking out a "patent medicine licence."

Lex.—We have not made any such statement, but our opinion upon the subject will be found in the *Pharmaceutical Journal* for June 9, 1883, p. 1025.

G. W. H.—(1) The specimen sent is *Geranium molle.* (2) *Leontopodium alpinum* (Compositæ).

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Hager, Messrs. Dott, Gorrie, Inquirer.

DR. REDWOOD'S PROCESS FOR LIQUID EXTRACT OF CINCHONA.

BY A. J. COWNLEY.

The great difference between the opinions expressed in reference to the process suggested by Professor Redwood for the preparation of liquid extract of cinchona bark, in the course of the discussion that took place after the reading of his paper, is sufficient evidence that there is room for further investigation of the subject, and this view was indorsed by the impression entertained by one of the speakers, "that they knew very little about bark." In any case it appeared desirable to ascertain how far the process now suggested by Professor Redwood as a substitute for the one which is official in the present British Pharmacopœia is calculated to realize the objects which he has defined as being most important and whether it is a substantial improvement on the existing process. I have therefore carried out some experiments to determine these points, and have obtained results that I will now proceed to describe.

As regards the kind of cinchona bark operated upon, I have acted upon Professor Redwood's decision that East Indian succirubra bark is the best to be used for preparing a liquid extract, and though not fully agreeing with this opinion, have not now ventured to offer any objection to it, since I am not aware that the "previous observations"* which led Professor Redwood to that decision have yet been made public. Some difficulty was experienced, however, in selecting for the purpose of my experiments "red cinchona bark of good average quality." In the absence of any criterion to serve as a guide in this respect and having regard to the extreme variability of this kind of bark,—the contents of alkaloids ranging from less than one per cent. up to more than ten per cent.,—as well as the absence of any definite or recognizable relation between the external characters of a sample and the amount of alkaloids contained in it, I concluded that it would be best to operate upon bark of previously ascertained alkaloidal contents, and to choose such as contained a medium percentage, as shown by the following figures:—

	Per cent.		Grains per lb.
Quinine	2·1		147
Cinchonidine	1·6		112
Cinchonine	2·03	or	$142\frac{1}{4}$
Amorphous alkaloid	1·00		70
Total alkaloids	6·73		$471\frac{1}{4}$

Liquid extract made from this bark by a process capable of effecting the entire removal of the alkaloids, and standardized so that 1 fluid ounce would correspond to 1 ounce of the bark, ought, therefore, in accordance with the above figures, to contain about $29\frac{1}{2}$ grains of total alkaloid per fluid ounce, with the several alkaloids in the following proportions:—

	Grains.
Quinine	9·2
Cinchonidine	7·0
Cinchonine	8·9
Amorphous alkaloids	4·4
Total alkaloids	29·5

This would be rather more than 5 per cent.—the proportion recommended by Professor Redwood; but for the purpose in view the bark was considered to be sufficiently near to the proper standard.

In operating upon one pound of this bark in the manner directed, I found that when 10 pints of liquid had passed through, the percolate still gave a precipitate when mixed with caustic soda in excess; the operation was therefore continued until the percolate had ceased to give this reaction. On reaching that point $13\frac{3}{4}$ pints of liquid had passed through. This percolate was sensibly acid, even while thus dilute, and when evaporated down to one pint was much more strongly acid. On cooling and diluting the liquor with water it deposited some brown flocculent material, which, when separated by filtration, washed and dried, was found to weigh $27\frac{1}{4}$ grains and to contain 1·1 grain quinine with traces of the other alkaloids. The filtered liquid evaporated to dryness left a residue of solid extract weighing $4\frac{1}{4}$ ounces, which was found on analysis to contain 12·96 per cent. total alkaloid.*

According to the directions given by Professor Redwood in his paper for preparing the liquid extract from this solid extract, it is easy either to obtain a preparation that shall contain 5 per cent. total alkaloid, or one containing in a given bulk exactly as much total alkaloid as the corresponding weight of bark operated upon. But to fulfil both these conditions it would be necessary to use bark containing exactly 6·25 per cent. total alkaloids. In the present case, for instance, 1 ounce of the bark contained nearly $29\frac{1}{2}$ grains of total alkaloids, and by dissolving to the volume of a fluid ounce as much extract as contained that quantity of total alkaloids ($227\frac{1}{2}$ grains), of course the fluid ounce of liquid extract would to that degree correspond to 1 ounce of the bark it was made from, and would contain 6·73 per cent. of total alkaloid. To bring it nearer to Professor Redwood's standard of 5 per cent., $168\frac{3}{4}$ grains of the dry solid extract was dissolved to the volume of one fluid ounce, and on analysis the product gave:—

	Grains.
Quinine	5·89
Cinchonidine	5·90
Cinchonine	5·69
Amorphous alkaloid	4·39
Total	21·87 = 5 per cent.

* Clearly there is a growing "fashion" in favour of red bark. We may, however, take the opportunity here of remarking that among the various recommendations of Indian succirubra bark, the one put forward by Professor Bentley, of its being "the sole bark recognized in the German Pharmacopœia," seems to be scarcely in accordance with the qualifying term "*præcipue*," which is used in that work.—ED. PHARM. JOURN.

* I was unable to obtain satisfactory results in the analysis of this extract according to the method directed by Professor Redwood. On treating 20 grains of the extract with caustic soda, a slimy precipitate was thrown down, and the liquid became so thick that it could not be filtered readily. After washing and drying this precipitate, it weighed only 0·92 grain, though it was only in part alkaloid, while the quantity of alkaloid was found by another method to be 2·59 grains. Part of this deficiency was in all probability owing to the viscous state of the extract solution when mixed with caustic soda, but in part it was a consequence of the solvent action of the water present. This was ascertained by operating upon a quantity of dry quinine sulphate containing 2·59 grains of alkaloid dissolved in one fluid ounce of water, and mixed with three fluid drams soda liquor and washing the precipitate so obtained. The dried precipitate obtained weighed only 1·97 grain showing a loss of 0·62 grain.

By comparing these results with those furnished by the analysis of the bark operated upon, it will at once be seen that the relative proportions of the alkaloids are different as compared with the original bark, and that there is in the extract a relative deficiency of quinine, together with a relative preponderance of amorphous alkaloid. There was, therefore, some reason to infer that the extract did not adequately represent the bark from which it was made, inasmuch as it contained a smaller proportion of the most valuable and important alkaloid quinine, and a much larger relative proportion of the less valuable amorphous alkaloid, which is by some considered to be objectionable from a medicinal point of view. In addition it will be seen that the quantity of solid extract requisite to make one fluid ounce of liquid extract representing one ounce of the bark, was very much larger than the quantity obtained from one ounce of bark, or 227½ grains instead of 115½ grains.

This leads to a consideration of the further desideratum, that in preparing liquid extract "the bark should be exhausted of its alkaloids by the process adopted," and it must be pointed out that as yet no evidence has been furnished that the suggested process is capable of effecting such a result. The device just referred to, of taking as much solid extract as contains a desired quantity of total alkaloids in order to make a certain bulk of liquid extract, is one very safe to rely upon for standardizing the amount of total alkaloid in the latter preparation; but since it has no kind of connection with the entire removal of the alkaloids from the bark used, the efficacy of the process in this respect must be tested in another way. In order to obtain some evidence on this point the total quantities of the several alkaloids in the solid extract above referred to were computed on the basis of the analysis and compared with the quantities contained in the bark from which it was made, as follows:—

	One pound of bark contained Grains.	4¼ ozs. of solid extract contained Grains.	Deficiency.
Quinine	147	64·57	82·43
Cinchonidine . .	112	64·70	47·30
Cinchonine . . .	142¼	62·30	79·95
Amorphous alkaloid	70	48·03	21·97
	471·¼	239·60	231·65

It is evident from these figures that there was not only a large deficiency in the amount of total alkaloid, but that the quantities of the individual alkaloids showed dissimilar deficiencies, and that, in short, while only one-half of the total alkaloids had been extracted from the bark it was chiefly in regard to the more important alkaloids that this loss was most considerable. Evidently, therefore, the proposed treatment with hydrochloric acid does not furnish a preparation that can be considered to represent cinchona bark in such a manner that a fluid ounce shall contain all the valuable medicinal properties of an ounce of that drug.

In making liquid extract by this process the bark consumed is only half represented as regards total alkaloids, for, as already shown, it would be necessary to take the solid extract from nearly two ounces of bark to make one fluid ounce of liquid extract containing as much total alkaloid as one ounce of the bark, while beyond this the total alkaloid in the liquid extract so produced would be much inferior, as regards the relative proportions of its constituents, to that actually contained in the bark itself.

To obtain further confirmation of this result the residual bark was submitted to analysis, and it was found to contain 4·49 per cent. total alkaloid. The following table gives a general *résumé* of these results, from which it will be seen that the residual bark contained nearly as much alkaloid as had been extracted by the process and that as regards the relative proportion of quinine it contained it was even better than before treatment:—

	One pound of the bark contained Grains.	Precipitated by water 27·3 grains. Grains.	Solid extract of red cinchona 4¼ ozs. Grains.	Residual bark contained Grains.
Quinine . . .	147	1·1	64·57	81·33
Cinchonidine .	112	—	64·70	47·30
Cinchonine . .	142·25	—	62·30	79·95
Amorphous alkaloid . . .	70	—	48·03	21·97

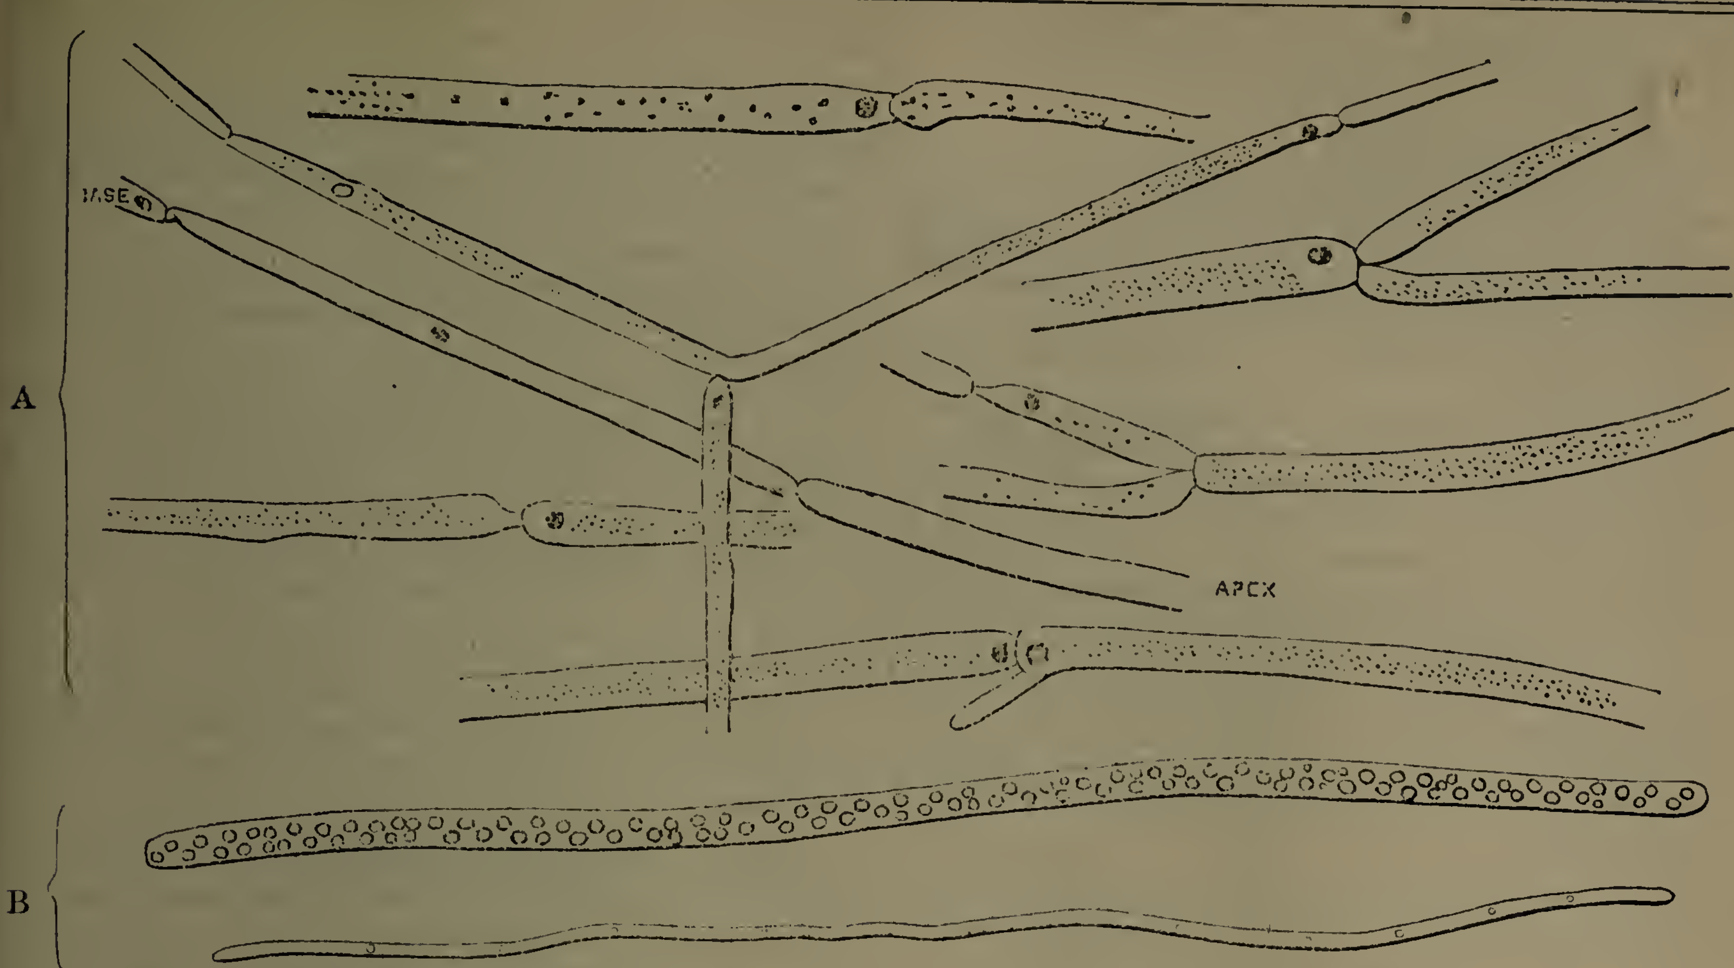
BEGGIATOA ALBA: THE SO-CALLED "SEWAGE FUNGUS."

BY ALFRED W. BENNETT, M.A., B.SC., F.L.S.,
Lecturer on Botany at St. Thomas's Hospital.

Under the name of "sewage-fungus," a peculiar organism is familiar to sanitary engineers as occurring abundantly and universally in the effluent water from sewage-works, forming dense flocculent greyish-white masses attached to the bottom and sides of the channel or to ordinary green algæ. Under the microscope it is seen to consist of an immense quantity of colourless threads, with but little or no chlorophyll, full of granular protoplasm, and containing a number of bright strongly refractive granular particles. This is *Beggiatoa alba*, Vauch., an interesting and remarkable organism.

The best description and drawing with which I am acquainted are by Zopf ('Die Spaltpilze,' Breslau, 1883, p. 76); but the specimens I have had an opportunity of examining differ somewhat from the typical form. Zopf describes the filaments as varying greatly in diameter, from 1 to 5 mm., as being unbranched and unseptated, and as characterized by the presence of strongly refractive globular particles, which have been determined by Professor Cohn of Breslau and Professor Cramer of Zürich to consist of pure sulphur. I find the filaments to be copiously branched, either dichotomously or laterally, and septated, either at the bases of the branches or elsewhere, and the cells to be frequently remarkably constricted above and below the septa. Still these low organisms are so often variable in points of structure of this kind, that further evidence of the constancy of these differences would be required before establishing a distinct species. The globules of sulphur I find most commonly situated one immediately below each septum; but sometimes towards the centre of a cell or more generally diffused. The systematic position of *Beggiatoa* is somewhat obscure. Zopf places it without hesitation in the Schizomycetes, with which it agrees in the absence of chlorophyll, and in a capacity for assuming different conditions, of which the ordinary form may be regarded as the leptothrix state. It also has corre-



A. *Beggiatoa alba* or sp. nov. observed in effluent from Sewage Works at Hertford.
B. *Beggiatoa alba*. From Zopf's figure in the 'Encyklopædie der Naturwissenschaften.' } Multiplied about 500 diams.

sponding bacillus, bacterium, coccus, and spirillum conditions. On the other hand it is certainly closely allied to the Oscillatorieæ through *Crenothrix*, if this genus is to be retained; and if at certain times of the year it develops chlorophyll, which I think is probably the case, there would be no good characters by which to distinguish it from that class. If the trifurcate division of Thallophytes, which is a modification of Sachs's, is adopted, into algæ, fungi, and protophytes, it will come under the third and lowest class.

The source of the sulphur contained in this organism is a very interesting question. It is a prevalent idea among sanitary engineers that the presence in water of the "sewage-fungus" is a sure indication of partially decomposed sewage. But this would seem to be not necessarily the case. Zopf describes it as occurring in the effluent water from manufactories, especially sugar factories and tanneries, and in thermal sulphur springs, as well as in drains. Luerssen ('Die Kryptogamen,' Leipzig, 1879, p. 24) gives as its habitat putrid water, noisome ditches, the effluents of manufactories, and mineral springs, especially all thermal sulphur springs, as those of the Alps and Pyrenees, Aix-la-Chapelle, baths at Vienna, etc. I have myself seen what I have no doubt to be *Beggiatoa alba* in large quantities on the waste ground about alkali works near Jarrow-on-Tyne. It therefore has probably the power of extracting the sulphur not only from decomposing organic matter, but also from mineral sulphates dissolved in the water; though the absence of chlorophyll would indicate that it is dependent on decaying organic substances for its carbon. Luerssen states that it has the power of developing sulphuretted hydrogen out of the sulphates in the water, and that water from thermal springs at Landeck containing this organism, preserved in a closed glass bottle for four months, contained from 5·07 to 7·24 cubic centimetres to the litre of sulphuretted hydrogen, as against 0·92 to 1·65 cubic centimetres per litre in the fresh water. But it is difficult to attribute this production of H_2S to the *Beggiatoa* in connection with the fact that it undoubtedly has the power of separating free sulphur. There can be no doubt that neutral sulphates are decomposed by organic matter in the water with separation of sulphuretted hydrogen or formation of sulphides; as is shown by the constant presence of protosulphide of iron in water containing decaying vegetable matter. But as sulphides contain a larger percentage of sulphur than sulphates, it is difficult to reconcile this process with the simultaneous elimination of free sulphur. Supposing that both sulphides and sulphites are found in the water, we might get free sulphur from the mutual decomposition of sulphurous acid and sulphuretted hydrogen, thus:—

$$2H_2S + SO_2 = 2H_2O + S_3.$$

In the locality where I had the opportunity of examining the *Beggiatoa* there is abundance of sulphates provided for its nutriment. The sewage of Hertford is carried into the river Lea after being treated by a modification of the process known as Anderson's, consisting essentially in precipitation by sulphate of alumina, lime, and protosulphate of iron; and it was from the open channel which conducts the water, after being so treated, into the Lea, that I obtained my specimens.

The growth of the so-called "sewage-fungus" must undoubtedly be regarded as evidence of the presence in the water of an abnormal amount of sulphates, derived either directly from sewage or from the substances used in precipitating it, or in other ways in manufactories. But there seems no reason to believe that it will itself have any injurious effect on the water. It is difficult to see how the sulphur, once set free, can again combine with hydrogen to form sulphuretted hydrogen as long as the organism is growing in the water. Indeed if allowed to accumulate, and periodically removed, it may tend to purify the water by abstracting from it some of the undue proportion of sulphur. Further examination of this interesting organism, and especially careful analyses of the ash, would be very desirable.

IMPROVEMENT IN THE EXTRACTION OF SULPHUR.*

BY CAMILLE VINCENT.

Sulphur is found in superficial deposits, resulting from volcanic eruptions, forming so-called "solfatares," or else in deep beds associated with marl, bituminous limestone, gypsum, celestine, etc., forming so-called "soufrières," which are the most important deposits of sulphur.

The principal "soufrières" are in Sicily and in continental Italy.

The ore is obtained in the simplest possible way, generally with a pick, and transported on the backs of the natives. The metallurgy of this ore consists in the partial combustion of the sulphur; the heat given off from the flame is sufficient to melt the entire mass and in this way the liquid sulphur is produced, which is then collected. In Sicily the sulphur is treated in a furnace to which the name of "calcarone" is given. This consists of an inclined circular bed, upon which the mineral is placed, and bounded by walls. The pile thus formed is covered with a sufficiently thick layer of the exhausted material in order to prevent the too active combination of the sulphur.

During the preparation of the pile, at suitable distances passages are left, in which fagots or bundles of wood are placed. The calcarone being thus prepared, the wood is lighted and the entrance of the air is so arranged as to prevent a too rapid increase of the combustion and a too great increase of temperature. After the operation has been continued for some time, the heap is cooled at certain points; then it is cooled at several other points until the fire is completely extinguished. By this process large quantities of sulphurous acid are produced, and especially is this the case when the wind influences the combustion and makes the cooking of the furnace difficult. This method of procedure is unhealthy and is productive of considerable damage by preventing all agricultural pursuits within a given radius, thus making it necessary to limit the length of time allowed for its production. It is, indeed, forbidden in Italy to burn the sulphur from the 1st of July to the 31st of December. The first six months of the year only are reserved for this work.

These calcaroni do not yield more than 50 and in certain cases 60 per cent., at most, of the amount of sulphur contained in the ore. The remainder serves as fuel and quantities of it pass off as sulphurous acid.

The crudeness of this process had for a long time been the cause of numerous researches, with a view of devising a method for the extraction of sulphur in a more rational and cheaper manner by employing some other fuel.

Attempts have been made by using hot air, by using steam under pressure, by superheated steam, and finally by the use of carbon disulphide for dissolving out the sulphur. All of these processes have had for their object the more rapid and complete extraction of the sulphur contained in the ore as well as to avoid the production of the sulphurous acid, and so to allow the continuance of the extraction during the entire year.

The first of these processes consists in filling chambers of masonry or kilns with the ore and in passing through the sulphur a current of hot gas, coming from a hearth fed by wood or by coal. In this way it is possible to prevent the formation of a considerable portion of the sulphurous acid, but the operation only takes place slowly and the heating of the mass is very irregular. A large amount of fuel is required; the manual labour is increased, so that the economy realized is of no importance.

The use of steam seemed at first to afford the best solution of the question, as the operation is very simple, very rapid, and the sulphur obtained is of the very best quality. The result is a product superior to that obtained with the "calcarone," and it does not produce any sulphurous acid.

But it has been found that these advantages were to a great extent counterbalanced by the expense of purchasing and preservation of the necessary materials used in conducting the process, as well as the large expense required for fuel.

The necessary plant consists of steam boilers and autoclaves for the receipt of the ore and other various accessories.

The water which is used for feeding the boilers is always bad and produces incrustations, so that this forms a serious objection to the use and to the taking care of this apparatus. Finally, the proportion of fuel is considerable, on account of the large consumption of steam required for the heating of the ore, and by the radiation of the apparatus where surfaces are exposed.

This process, therefore, is not applicable in all cases, as the results, although superior to those of the "calcaroni," are not commensurate to the expense required for the purchase of fuel, the increase of manual labour, the deterioration of the apparatus, and of the consequent diminution of the capital.

The treatment of the ore by carbon disulphide, although theoretically very rational, presents such objections when used that it may just as well be regarded as impracticable. We find this compound volatilizes so easily that its management becomes very difficult, and dangerous as well, and that the expenses of the process are largely increased. Besides, a particular article is essential, which is quite expensive of itself.

All these difficulties have prevented the different processes thus far described from coming into general use, as had been expected, and the sulphur is still almost entirely extracted by the fusion in the calcarone.

About 1805, M. Thomas made attempts to extract the sulphur from its ore by immersing the ore in saline solutions heated up to a convenient temperature. Later on, in 1867, Balard suggested the use, for the same purpose, of the mother-liquors of saline marshes, rich in magnesium chloride. Finally, in 1868, Deperars took out an Italian patent for the extraction of sulphur by immersing the mineral in a solution heated up to 10° or 20° above the freezing point of this body, thereby effecting the separation of the earthy material. The liquid curd was a solution of calcium chloride.

The apparatus which was patented consists of a spherical boiler or chamber of cast metal, capable of holding 2000 litres, having a discharge stop-cock, and above this is a vertical cylinder into which, by means of a crane, a perforated basket of sheet iron filled with the ore is lowered and allowed to rest on the grate.

The apparatus is fitted into a furnace, so that the boiler may be directly heated, while the cylindrical portion becomes surrounded with the heated gases as they pass on to the chimney. The basket, filled with the ore, lowered through the cylinder, becomes immersed in the solution of calcium chloride which is heated up to 130°. The sulphur melts and collects in the lower portion of the boiler, from which it is drawn off by the discharge-cock and received into moulds. When it is ascertained that the ore is freed from the sulphur, the basket is elevated by means of the crane and immediately lowered into a cylinder filled with water, heated in the centre of the furnace, in order to wash the residue, and thus to preserve the saline solution with which it has become covered. This water serves to counterbalance the evaporation in the extraction apparatus.

At this time it was difficult to obtain calcium chloride at reasonable prices at the locality where the sulphur was extracted. Besides, other difficulties followed in the carrying out of this process, so much so, that in 1867 the patent was abandoned and has since become public property. Quite recently this process has been taken up by De la Tour Dubrenil, and put into practice with considerable success.

* From the *Bulletin de la Société Chimique de Paris*, xl., 528. Reprinted from the *Oil, Paint and Drug Reporter*.

To-day, calcium chloride has become very cheap, in consequence of the great development of the soda ash industry by the ammonia process. At present it can be transported from long distances, and its cost delivered on the ground of the sulphur mines in Sicily should not exceed 9 francs by the hundred kilograms (220 lbs.). The apparatus used by De la Tour Dubrenil may be described as consisting of two rectangular boilers made of sheet iron, having a capacity of about 2 cubic metres (2 metres by 1·30 metres and ·75 metres in height). The bottom of these boilers inclines one-tenth. They are mounted on a furnace so that each one of them can in turn be heated by the same hearth, which is fed by either lignite, coke or coal. The ore is piled or heaped up in one of the boilers, a solution of calcium chloride so concentrated that it will not boil below 120° is poured in and heat applied. The sulphur melts little by little, and on opening a valve at the bottom the liquid is collected directly in moulds.

The entire operation with the ore in rocks lasts about two hours. Towards the end of the operation the sulphur will no longer flow when the valve is opened. The bath of chloride is then turned off into the adjoining boiler, which has been previously charged with ore, half of the liquid is poured off by means of the connecting cock between the two boilers, the remainder is received into a vat situated under ground and is elevated by means of a pump.

The residue is quickly washed in order to remove the calcium chloride with which it is impregnated, and the diluted liquid thus obtained serves to compensate for the evaporation of the bath. As soon as possible the heat is applied to the second boiler already charged, and the exhausted ore removed from the first one in order to prepare for a new charge.

The work is so accomplished that the operation may be practically considered a continuous one.

The sulphur obtained in this way contains not more than ·001 to ·002 per cent. of impurities, while that obtained from the "calcarone" contains up as high as 2 to 3 per cent.

Besides, the residue does not retain more than 4 to 5 per cent. of sulphur by this process. In this process, certain of the ores become completely disintegrated, and in consequence in the powdered sulphur there were frequently found portions of earthy matter. De la Tour Dubrenil was, therefore, obliged, in order to obviate this great difficulty, to completely modify their apparatus.

The new arrangement which has been adopted can be applied to the treatment of all varieties of ores.

The boilers are arranged horizontally and divided through the centre, that is lengthwise, by a large drain, which alone has the desired slope in order to permit the flowing off or draining off of the sulphur. On the edges of this drain two vertical gratings of iron are arranged which hold the ore on each side and allow the centre to be entirely free. These gratings are made of bars of iron 2 millimetres in thickness and 25 millmetres long, and placed 3 millimetres apart. In consideration of this new arrangement it is possible to break all kinds of ore in this apparatus. In fact, even powdered mineral, such as the *débris* resulting from grinding, which is very rich, and which is designated in Sicily by the name of *sterri*. This *débris*, which up to the present time has lain neglected on the ground where the mineral is treated, can now with great facility be made to yield this sulphur in this apparatus.

This *sterri* is always richer than the general portion of the ore mined, because during the grinding or breaking up of the mineral the rock breaks and naturally divides according to the layers which are rich in sulphur, as they offer the least resistance. In consequence of its friability, the sulphur becomes partially reduced into dust, which thus forms a large portion of the *débris*.

At the Tronica Mine, in the Province of Caltanisetta, of Sicily, the ordinary mineral yields 20 per cent. of sulphur by the treatment in the calcium chloride bath, while the "sterri" from the same mine gave 72 per cent.

The ordinary run of ore in Sicily yields 12 to 13 per cent. of sulphur, with the "calcarone" reaching 15 to 17 per cent. in certain mines.

In comparative tests made with the same ore, 10 to 12 per cent. of sulphur were obtained in the treatment with "calcarone," and 19 to 23 per cent. by fusion in the calcium chloride bath.

It has been noted for some time back that very rich ores gave bad results when treated in the "calcarone:" in most cases the combustion is too rapid, and the sulphur becoming brown and pasty by the overheating flows only with difficulty.

It is necessary, therefore, in treating such ores to mix them with inert substances, and the yield in such cases does not correspond with the original richness.

On the other hand, the rich ores can be treated very advantageously by the chloride bath. From the results obtained by De la Tour Dubrenil, after treating a large quantity of "sterri," it was found that 12 fr. 75c. was about the price for the extraction of a ton of sulphur in cases where the average yield of the ore was 33 per cent. of the original weight. The price of the treatment of a charge of the apparatus, which is about 1000 kilograms, may be figured as follows:—

35 kilos of fuel (from coal mixed with lignite)	fr. 1.05
14 kilos of calcium chloride, at 9 fr. the 100 kilos	1·25
Labour	1·25
Contingencies and other expenses 20 per cent.	0·70
Total	4·25

That is, in order to obtain a ton of sulphur it is necessary to charge the apparatus three times, which places the price of extraction at 12 fr. 75c. An operation with the "sterri" requires an hour and a quarter for fusion, a quarter of an hour for running the sulphur out, and finally, an hour and a half to wash the residue, collect the solution, empty the boiler, and to replace the movable gratings in their original positions.

De la Tour Dubrenil have already placed quite a number of their apparatus in operation principally for the treatment of these "sterri." There are three at the Tronica Mine, in the Province of Caltanisetta, two at the Grottarossa Mine in the same province, two at Permie, near Recalmute, two at the Crocca Mine.

The process which we have just examined has several important advantages, among these are the following:—

First. The extraction of the greater portion of the sulphur from ores of all kinds, even from "sterri," the use of a small amount of fuel, or at least of a fuel which is inexpensive. Second. A continuous extraction having but little effect upon the atmosphere. Third. The suppression of sulphurous acid, thus making it possible to extract the sulphur continuously throughout the year. Fourth. The treatment of the ore in proportion to the mining and the shipping of the sulphur at times favourable to its transportation.

DETECTION OF CHLORINE, BROMINE AND IODINE.*

BY C. THOMPSON.

In the *Chemical News* (vol. xlviii., p. 296) there appeared a process by Mr. Jones, for detecting chlorine, bromine and iodine in presence of each other. The process was

* Report on Analytical Chemistry read before the School of Pharmacy Students' Association.

as follows:—"Place a small quantity of the mixture to be tested in a good sized test-tube, add a few pieces of manganese dioxide and then a little water. Add now 1 drop of dilute sulphuric acid (1 part acid to 10 parts of water), a brown tinge indicates the presence of iodine. Boil the mixture and confirm the presence of iodine by the violet vapours in the upper part of the tube. Continue the boiling till these vapours cease to appear, then add another drop of sulphuric acid and boil again until they cease. If necessary, repeat this addition of acid and boiling until violet vapours have entirely ceased. Now add about 2 cubic centimetres of the dilute acid and boil again; brown vapours indicate bromine, Continue the boiling until the vapours no longer smell of bromine, then add another cubic centimetre of dilute acid and boil again. When the vapours no longer smell of bromine, allow the tube to cool thoroughly, add an equal bulk of strong sulphuric acid and warm; a green gas bleaching a piece of moist red blotting-paper at the mouth of the tube indicates chlorine Occasionally some more bromine comes off on the addition of the strong sulphuric acid, but if so, it is soon got rid of and is succeeded by the chlorine, which is chiefly evolved on heating the mixture. As, moreover, red blotting-paper is far more quickly acted on by chlorine than by bromine there can be no difficulty in distinguisning between the two." Mr. Jones also adds that he has found this process to compare very favourably with others. This process is somewhat similar to that recommended by Vortmann, except that sulphuric acid is the active agent instead of acetic acid. Mr. Barnes has shown that unless very great care is exercised, Vortmann's process is not trustworthy; so that it would not at first sight seem likely that Mr. Jones's process in which sulphuric acid is to be used would answer much better.

Experiments tend to confirm this statement. If there be a large excess of iodide over that of the bromide present in the solution or mixture to be tested, or if, *vice versâ*, the bromide be in excess, then this result seems to follow in nearly every instance; viz., that the vapour of that halogen which is present in a very small quantity relatively to the quantity present of the other halogen is likely to be overpowered by the vapour of the latter. When relying only on the colour of the vapour it was found that when the proportion of the iodide to the bromide was less than 1 to 14, the iodine could not be detected, and even when paper moistened with starch solution was used, there was no indication of iodine if the proportion was less than 1 to 20. As regards detecting bromine, following the process, and relying on the colour of the vapour only, it was found that the bromine could not be detected if the proportion between the bromide and iodide present was less than 1 to 15; when filter-paper moistened with iodide of potassium and starch solution was used, it was possible to detect the bromine so long as the proportion between the bromide and the iodide is not less than 1 to 22.

When the chloride is present in small quantities relatively to the iodide and bromide, or more especially if it be the bromide which is in excess, it is not easy to detect it by this method; for when the bromide is in large excess it is not all driven off by the addition of the dilute sulsulphuric acid, so that when the strong acid is added the remainder comes off and takes along with it the chlorine.

As a rough way of detecting the presence of either one or of all three of the halogens, when present in fair quantity relatively, this process will answer, more especially if the colour of the vapour be not alone relied on, but filter-paper moistened with starch solution for the iodine and with iodide of potassium and starch solution for the bromine be used.

As a delicate test for detecting the presence of small quantities of either one of the three halogens in presence of the other two it is not to be relied on.

THE SO-CALLED BISMUTH BREATH.*

BY WILLIAM REISERT, PH.G.

Bismuth oxynitrate, when taken into the human system, often imparts to the breath a very perceptible, and disagreeable garlic-like odour, which is very annoying, not only to the person who has taken the salt, but particularly disagreeable to the persons with whom he may come in contact. This odour has been attributed by writers to be caused by impurities in the bismuth salt, such as arsenic and tellurium, and some have asserted that the chemically pure bismuth salt itself produces the odour. The subjoined experiments will add to the already known facts concerning the cause of the production of this odour, namely, the ingestion of tellurium, which element occurs as an impurity in many samples of bismuth oxynitrate.

Chemically pure sesquioxide of bismuth was prepared by dissolving the commercial oxynitrate in chemically pure nitric acid, and precipitating with an excess of water. This operation of redissolving and reprecipitating was repeated twice, and the precipitate was then strongly heated in a porcelain crucible to convert it into bismuth sesquioxide, and at the same time to volatilize any arsenic which might have been contained in the substance. Tests for arsenic and tellurium in the resulting sesquioxide failed to denote their presence.

The bismuth sesquioxide thus purified was administered to five persons under the same, and under different conditions as to dose and time. From 0·5 to 1·0 gram was given three times daily for six days. No garlic-like odour could be recognized in the breath.

To investigate the action of arsenic in the production of this odour in the breath, arsenious oxide was taken by myself, in doses of 0·003 gm. after each of the three daily meals for three days. On the fourth day, on account of the griping pain produced in the abdomen, and a violent diarrhœa, only two doses were taken. There was not the slightest garlic-like odour perceptible in the breath.

Tellurium is comparatively rare, and is contained in many of the ores of bismuth. The mineral tetradymite contains as much as 49·79 per cent., wehrlite, 29·74 per cent., and joseite, 15·93 per cent. of the element. In a sample of metallic bismuth from Bolivia, Schneider† found 0·14 per cent. of tellurium. Brownen‡ found tellurium in the commercial bismuth oxynitrate, but it was not present in large quantity. On account of difficulties in its separation from bismuth, it often occurs as an impurity in the commercial bismuth oxynitrate, yet in most cases the quantity present is very minute. If more care were used in the preparation of the commercial oxynitrate, less would be heard of the so-called bismuth breath. Repeated precipitation and washing will entirely remove the obnoxious element.

As early as 1824 the odour produced by the ingestion of tellurium compounds was noticed by Gmelin.

In 1853 Hansen§ investigated the cause of the production of the odour. This investigator experimented upon himself and a friend, and upon dogs, with potassium tellurite. This salt, in doses of 0·030 to 0·080 gm., taken by himself an hour before each meal, gave the garlic-like breath within a few minutes after the first dose, and this odour soon became so strong that he had to seclude himself from society. He continued the doses during seven days, his friend continued the doses for two days with similar effect, and noticed the odour in his breath for eight days afterward.

It is also stated that Wöhler, when investigating the volatile telluride of ethyl, noticed this same odour in his breath, and one night, when perspiring freely, the odour

* From the *American Journal of Pharmacy*, April, 1884.

† *Journ. f. Prakt. Chem.*

‡ *Pharm. Journ.*, October 16, 1875; *Amer. Journ. Phar.*, 1876, p. 133.

§ Liebig's *Annalen*, lxxxvi., p. 208.

of the perspiration was almost unbearable. In the experiments on dogs the garlic-like breath was perceptible after one minute. Hansen quotes Gmelin as having in 1824 given tellurous acid to a dog and a rabbit. The rabbit only was killed, and on dissection gave off a garlic-like odour.

Sir J. Simpson* records a case in which a divinity student inadvertently swallowed a dose of tellurium, which was followed by the evolution of such persistent odour that for the remainder of the session the patient had to sit aside from his fellow students.

The experiments in this direction made upon several friends, and also upon myself are as follows:—

Tellurous oxide (TeO_2) was prepared by treating metallic tellurium with nitric acid, evaporating to dryness and igniting the product. Some of the resulting tellurous oxide was taken by myself in doses of 0·005 gm. each. Three doses were taken on May 8, 1883, at 1, 4, and 7 o'clock p.m. In fifteen minutes after the first dose the breath had a strong garlic-like odour, and in an hour a metallic taste was observed. An hour after the second dose the urine and sweat had the garlic-like odour, which was also observed in the fæces on May 12. The metallic taste was observed for seventy-two hours, and the garlic-like odour in the urine for three hundred and eighty-two hours, in the sweat for four hundred and fifty-two hours. in the fæces for seventy-nine days, and in the breath it was still present, though very faintly, after two hundred and thirty-seven days.

In order to determine the smallest quantity of tellurous oxide which would be required to produce the garlic-like odour the following solutions were made:—

I. 0·001 gm. of tellurous oxide was dissolved in potassium hydrate and sufficient distilled water to obtain 100 cubic centimetres. 5 c c. contain 0·00005 gm. tellurous oxide.

II. 0·00025 gm. of tellurous oxide was dissolved with the aid of a little hydrochloric acid in sufficient distilled water to make 100 c.c. 5 c.c. are equal to 0·0000125 gm. of tellurous oxide.

III. Made like the preceding, but diluted to 200 c.c. 5 c.c. are equal to 0·00000625 gm. tellurous oxide.

IV. 0·0001 gm. tellurous oxide, sufficient hydrochloric acid and water to measure 100 c.c. 5 c.c. are equal to 0·000005 gm. tellurous oxide.

V. Like the preceding, but diluted to 500 c.c. 5 c.c. are equal to 0·000001 gm. tellurous oxide.

VI. 100 c.c. of solution V. was diluted with 100 c.c. of distilled water; each c.c. represents 0·0000001 gm. tellurous oxide.

These solutions were given to a number of young men; but no one was experimented upon a second time.

I. After one dose of 5 c.c. of this solution, the garlic odour became perceptible in the breath in thirty-five minutes and lasted about seventy-five hours.

II. Three doses of 5 c.c. each were taken after three succeeding meals. The odour was noticed in the breath thirty minutes after taking the third dose, and continued about sixty-six hours.

III. Five doses of this solution of 5 c.c. each were taken after five succeeding meals, when the odour was soon noticed, and lasted about ninety hours.

IV. After six doses of 5 c.c. each, the odour was quite distinct; three additional doses were taken and the odour lasted ninety-six hours.

V. Five doses of 5 c.c. each were taken after five consecutive meals; the odour was noticeable in forty-five minutes and lasted seventy-three hours.

VI. After one dose of 5 c c. the garlic odour was perceptible in seventy-five minutes and lasted about thirty hours.

Smaller quantities of this solution were then given, namely, 1 c.c. to each of two young men, 2 c.c. to two persons and 3 c.c. each to three persons; but no garlic-like odour could be detected.

* Blyth, 'Manual of Chemistry,' Lond., 1879.

The nature of the compound which possesses this garlic-like odour is, as yet, not understood, although Hansen attributes the odour to be caused by a volatile organic compound of tellurium like the telluride of ethyl, which is given off by the lungs and skin. Both methyl and ethyl telluride have a garlic-like odour.

In this investigation the breath of myself, which was exceedingly strongly impregnated with the garlic-like odour, was for several hours passed through a tall column of distilled water contained in a wash bottle, and the water afterward tested for compounds of tellurium, but not even a trace of this element could be found. However, from the minute quantity of the element which is required to produce this odour one would hardly expect to find by qualitative testing even the merest trace of the element in the breath. Necessarily, the presence of tellurium in such a minute quantity in the great majority of samples of the bismuth oxynitrate would prevent its detection by any of our chemical tests. From this failure to detect tellurium most likely have arisen the many statements* of its non-presence in the commercial bismuth oxynitrate. The physiological test seems to be the most delicate, as it has been shown that in this way as little as 0·0000005 gm. or $\frac{1}{125000}$ of a grain of tellurous oxide, equal to 0·0000004 gm. or $\frac{1}{160000}$ of a grain of the metal, may be detected.

In these experiments idiosyncrasy seems not to have had any influence at all. Every one to whom the tellurium compound was administered in sufficient quantity was affected with the garlic-like odour.

CINCHONA ROBUSTA.

The following passage concerning this hybrid appears in the recently issued 'Report on Kew Gardens for 1882':—"In the Kew Report for 1881, pp. 25, 26, I referred to the hybrid between *succirubra* and *officinalis*, which seems in the East first to have made its appearance in Ceylon, and thence to have been introduced by seed into the Sikkim plantations.

"This form has, during 1882, given rise to a rather protracted correspondence with the Madras Government. Mr. Cross, who was employed by the India Office to convey the Columbian barks from Kew to Southern India, insisted that the two supposed hybrid forms grown on the Nilgiris, under the names of *pubescens* and *magnifolia*, were not hybrids but distinct species, of which the seed had been sent by himself from the slopes of Chimborazo. After some shifting of opinion he seems finally to have settled down to the statement that *magnifolia* was the cinchona called in the Chimborazo bark district 'Pata de Gallinazo,' that *pubescens* was true *succirubra*, and that the *succirubra* of the Madras plantations was *micrantha* (grey bark).

"In all these identifications his recollections of plants seen no less than twenty years before seem to have misled him. Unfortunately, his views were, to a certain extent, adopted by the eminent quinologist, Mr. Howard, and it therefore became necessary to critically examine them, as such gigantic errors in nomenclature could not but very seriously affect the future policy of administration of the Madras Cinchona plantations.

"Under instructions from the Madras Government, very copious and carefully prepared sets of all the cinchonas cultivated in the Nilgiris were despatched to Kew, both by Colonel Beddome and by Surgeon-Major Bidie, the Superintendent of the Madras Central Museum. They were very thoroughly examined, and there appeared no valid reason for disputing the accepted names under which the plants had been grown or for adopting those assigned to them by Mr. Cross.

"The authentic specimens of the Pata de Gallinazo, collected by Spruce, and described by him in his official report, are preserved in the Kew Herbarium. They have been subsequently identified at Kew by Spruce

* Dr. Squibb, *Ephemeris*, Sept. 1882.

(confirmed by Howard) with *C. erythrantha*, Pav., and Triana, the most recent monographer of the genus, has referred this species as well as Spruce's specimen to *C. pubescens*, Vahl. Neither the *magnifolia* nor *pubescens* of the Nilgiri plantations can in any way be confounded with *Cinchona pubescens*, Vahl, but are, no doubt, as has always been contended, marked members of the variable series of hybrids which appear to invariably arise in plantations where *officinalis* and *succirubra* are cultivated in proximity.

"Mr. Cross's other two conclusions proved equally baseless. As, however, these questions of synonymy had excited a good deal of perplexity in Ceylon as well as in Southern India, I suggested to the Government of Madras that Dr. Trimen, the Director of the Royal Botanic Garden, Peradeniya, should be invited to visit the cinchona plantations of the Madras Government, in order to bring about if possible some uniformity of nomenclature in the forms and species of cinchona cultivated both in Ceylon and Madras. This he accordingly did, and he has given the results of his exhaustive study of the whole question in a very able and lucid report (dated June 30, 1883) which, representing as it also does, the opinions arrived at by the Kew staff, appear to me to finally dispose of the whole subject. Both the names *pubescens* and *magnifolia* Dr. Trimen, for reasons which he gives, proposes to discard in favour of *robusta*, which is in use on some estates in India, and 'is now commonly employed in Ceylon for the trees in question.' Dr. Trimen describes those he saw on the Nilgiris in the following words:—'I found the forms to be just those so common in Ceylon plantations. Generally robust well grown trees, larger, hardier, and healthier than either the *officinalis* or *succirubra*, among which they were scattered and often flourishing where neither of them can thrive. Botanically, there was the same range of variety, the extreme form in one direction, with its dark green smoothly shining leaves, closely approaching some of the large-leaved forms of *C. officinalis*; and that in the other direction with its larger, paler, thinner leaves more or less pubescent beneath, so close to the hairy form of *C. succirubra* as to be often with difficulty distinguished from it. Between these, as regards colour and pubescence, were many intermediates, though undoubtedly, with a little ingenuity, the whole can be thrown into two groups.'

"He further adds:—'We have direct testimony of its origin. I am assured by planters of credit that they have grown both glabrous and pubescent *robusta* from seed of ordinary *officinalis*, and that it is by no means unfrequent for seedlings of them to appear in seed-beds on estates where no trees but *officinalis* and *succirubra* occur. I have myself seen seedlings of *robusta* self-sown where there are no parent trees of the sort whence they could have been derived; and at one time I was inclined to regard it merely as a variety of *officinalis*. There are, I think, grounds for believing that *succirubra* generally supplies the pollen, and is therefore the male parent, both in the case of *robusta* (*succirubra* and *officinalis*) and *anglica* (*succirubra* and *cal saya*).'"

AMERICAN MUSK.*

BY R. S. CRISTIANI, PHILADELPHIA.

There has been a good deal of literature on this subject for two or three years past, much of which has been written by myself, and which has, I believe, attracted some notice both here and in Europe, for to obtain a good substitute for the very costly Tonquin musk has long been an object of great importance in all business countries, and the principal object of my writings has been to place the article in commerce, that all who desire it may know where to procure it.

The style "American Musk" is a title I have given it, as the animal from which it is obtained is indigenous to this country. This is the well-known rodent, the musk-rat (*Fiber Zibetica*), which frequents the streams and marshes of nearly all the States and Canada, having habits similar to the beaver. The musky secretion is found in two small sacs situated below the anus and near the genital organs. It usually adheres to the skin when removed, and is collected in a very indifferent way, if not thrown away as worthless by those who handle the pelts, as it is desirable they should be as free as possible from the odour.

This animal, when plentiful, is trapped for its skin—the fur being quite fine and soft—and shipped in large quantities to Europe, where they have great skill in dressing and dyeing furs, and it is made to imitate more expensive goods, such as seal, otter, etc. The winter and spring are the seasons that this trapping mostly occurs, and the spring is the only season when a supply of the musk pods can be obtained.

I have mentioned that there has not been any systematic attempt made to collect and prepare this valuable substance, except by myself, and with my many duties I have not been able to give it the attention it certainly deserves; yet I have had much correspondence on the subject here and from Europe, and especially from London, where there has arisen some demand for the article, owing principally to my efforts, but my time to devote to the subject has been limited and many opportunities to forward the subject unavoidably neglected. One reason why this valuable article is neglected, is the great ignorance of the persons who collect it, as they fail to take off the sacs carefully and often leave a quantity of membrane and fat adhering to them. Moreover, they have no knowledge of a proper mode of preparation to prevent decay, and the attack of insects, etc., so that the article would keep and be fit for sale at all seasons, for when the weather moderates they often find it unfit for use and worthless. Preservation is all important, if this musk is to be an article of commerce, and I think it soon will be; but it can scarcely be expected that such will be the case if it can only be procured two or three months in the year.

Let it not be supposed that I claim for the American musk all the properties of the true musk, far from it, for that valuable drug stands at the head of all analogous substances, having qualities that are not found in any known substance. But as a substitute in many manufactures, such as toilet soaps, and some secondary articles of perfume—and perhaps some flavours—I know of no article that is as good a one, and in soaps particularly it is invaluable, I having furnished it to some of our large manufacturers for some seasons.

The object of my present article is to call more attention to the collection of the musk-rat pod, in the States and Canada, as the season will soon open for the trappers, and the pelts will arrive at the usual centres in the late winter or early spring, and that those who deal in and handle them may see a source of profit in saving the odorous sacs. Should those who are interested in the article want further facts, they can correspond with me.

* From the *Canadian Pharmaceutical Journal*, April.

AMERICAN DRUGS.*

BY J. MOELLER,

Botanist and Microscopist of the Imperial Forest Institute, Mariabrunn, near Vienna.

(*Continued from page 865.*)

TONGA.

Coarsely cut, partially pulverized stalks of two different and easily distinguishable plants. The mixture has a strong odour reminding one of fenugreek.

The greater bulk of this drug consists of irregularly-shaped fragments of the stalk of a plant, seldom exceeding 2 cm. in length, sometimes, perhaps, as thick as a man's finger, very light and porous on the cut or broken surfaces or barkless portions, covered with a cork-coloured or dark brown bark; or of round stalks of the thickness

* Reprinted from the *Therapeutic Gazette*.

of a quill and ribbed lengthwise; or of flat pieces of bark, which, to judge from their size and form, evidently belong to said fragments. A glance at the horizontal section of one of these pieces with a magnifying glass proves distinctly that the varied shaped component parts belong to one and the same monocotyledonous species. The stem is composed of closely arranged bundles of dense fibres and covered by a comparatively thin bark traversed by hard, whitish streaks. This part of the drug has a specific odour and a delicate taste, slightly reminding one of vanilla.

Microscopic Characters.—The peridermis consists of five to eight rows of flat cells, some of which are thin-walled, the majority, however, being thickened almost to obliteration. The cells of the bark parenchyma are large and thin-walled, scarcely 0·5 mm. broad and covering but a small area. In older plants they reach 2 millimetres in width and have numerous irregularly disposed fibres which are, each of them, distinguished by a well-developed bast bundle presenting a kidney-formed section, in the concavity of which, which always faces inwards, are a small number of narrow tracheæ. A few isolated, spindle-shaped, strongly solidified bast fibres, 0·025 mm. in diameter, are to be found irregularly distributed amongst the parenchyma. The vascular bundles of the plant are

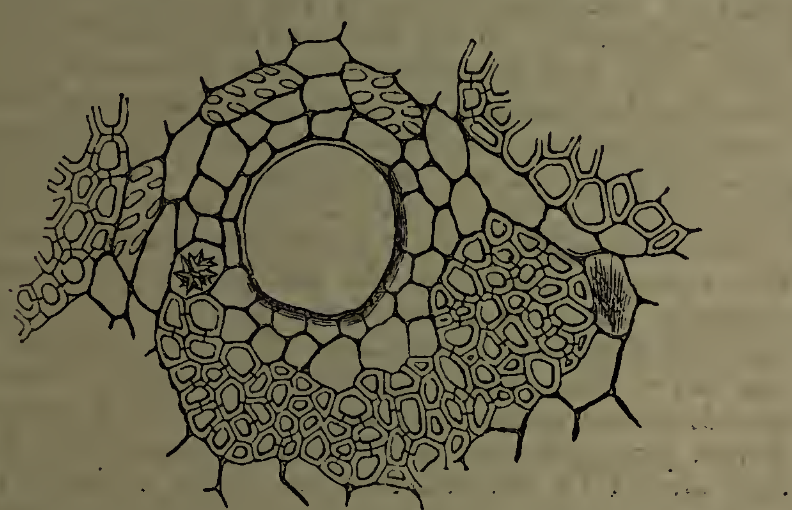


Fig. 14.—Vascular bundle from the central portion of the stalk of *Rhaphidophora Vitiensis.*

distinct from the peripheric fibres owing to the different location of the bast and the greater development of the wood, in which occurs a single vessel, or more seldom a pair of vessels, distinguished by a broad lumen (0·15 mm.). Raphidæ and glandular ducts are found within the principal parts of the stem and especially in the bark parenchyma.

This ingredient of the tonga is derived, as Holmes (*Pharm. Journ. and Trans.*, 1880, p. 889) had first suspected, and as has since been repeatedly proved, from a species of Aroid found in the Fiji and New Hebrides Islands, and known under the name of *Raphidophora vitiensis*, Schott. It is a variety of the *Raphidophora pertusa*, Schott, *Monstera pinnatifida*, C. Koch, found on the coast of Coromandel, in Ceylon, Java, Timor, and in those parts of Australia which lie within the tropics. N. E. Brown, in *Gardner's Chronicle*, designates *Epipremnum mirabile*, Schott, *Raphidophora lacera*, Hassk., as the plant from which this ingredient of tonga is obtained; but this is probably an error, since the latter variety has hitherto been found in Java only, while we know that tonga was first produced and brought from the Fiji Islands. These two varieties are, however, closely allied. They belong to the forms of Araceæ which A. Engler distinguishes by their double-rowed leaves, by their branches ending in a flower, and in each vegetation period springing afresh from the shoulder of the leaf again to a flower. The Raphidophora of the Fiji Islands, called by the natives "nai-yalu" or "walu," is a creeper whose vines, to judge from the fragments thereof as found in commerce, attain the thickness of a man's thumb, at least.

The other and less bulky component part of this drug, consists of small particles of bark, seldom as large as a finger-nail, and not more than 1 millimetre in thickness. The outer side of this bark is scaly, and in colour it varies from an ochre yellow to a tile-brown hue; the inner side is dark brown and wrinkled. It is a fine-grained, brittle bark, showing a chocolate-coloured section sprinkled with bright spots or points, and is wholly insipid and odourless.

Microscopic Structure.—The corky layer, which is no thicker than paper, is composed of cubic cells, with walls almost always very thin on the inner side, but occasionally thickened. This coating lies immediately contiguous to

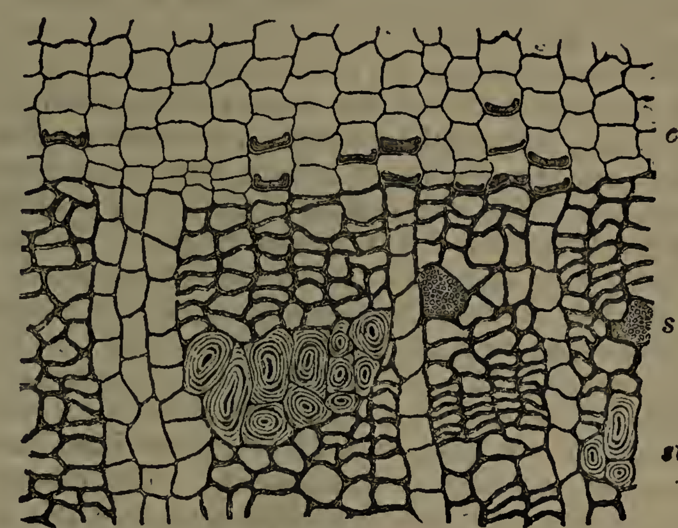

Fig. 15.—Section through the bast of *Premna Taitensis*. *c*, cork; *s*, sieve-plate; *st*, stone-cells.

the inner bark, which is traversed by one- to three-seried medullary rays, the alternating spaces between which seldom exceeding 0·5 mm. The bast rays consist of alternately arranged layers of parenchyma and sieve tubes; the membranes of both are dense, present an almost gelatine-like appearance, and are wholly devoid of bast fibres. On the other hand, groups of parenchyma often become sclerotic, which change is frequently accompanied by a moderate increase of their elements, the form of which, however, is not materially changed. The density of the walls of these, although formed of the most delicate layers, increases to an almost complete solidification, but they are still perforated by numerous minute pores, visible only under a very powerful microscope. Where the stone cells of neighbouring groups come in contact with each other, which, by the way, but seldom occurs, the medullary ray passing through them becomes sclerotic. Nearly all the medullary ray cells, as also many of those of the bast-parenchyma, are heavily charged with crystal sand or rhaphides. The sieve-tubes are somewhat more open; their transverse plates are occasionally to be seen in the section of the bark itself. (See Fig. 15.)

Mueller says that this ingredient is the bark of the *Premna taitensis*, DC. (*Pharm. Centralb.*, 1881, p. 548), a species of the Verbenaceæ found on the Society Islands, and called "aro" by the natives, and in this he is corroborated by its anatomical structure. (Compare Tectona, J. Mueller, 'Anatomy of the Barks,' p. 176.)

The plant is a shrub or small tree, the smaller twigs of which are somewhat sticky; its leaves, which grow to the length of 8 cm., are oviform, shortly acuminate, heart-shaped at the base, smooth and naked on both surfaces, and shiny on the upper side. The stem of the leaf, as also that of the blossom, is, to some extent, hairy. The flowers are very small and arranged in large groups at the end of the twigs on which they are found. The calyces are slightly cup-formed, almost double-lipped. The small whitish blossom contains four stamens attached to the tube. The fruit is a pea-formed berry, containing one seed.

It is and has long since been well known, that the leaves of certain other varieties of *Premna* (*e.g.*, *P. fœtida*, Reinw., *P. integrifolia*, L.) are used as food, particularly for flavouring purposes, in the Sunda and Molukka Islands and in East India.

In view of the variations (see Gehe and Co's Commercial Report, September, 1880) in the samples of this drug on its introduction, it is perhaps necessary for me distinctly to state that the samples of tonga which I have at various times received from America have always been found to be exactly alike and to contain invariably the two ingredients mentioned alone, and never leaves.

The London doctors, Ringer and Murrell, first recommended this drug as a remedy for neuralgia (see *Pharm. Centralb.*, 1881, p. 30) and it soon attained great notoriety.*

The *Lancet*, March, 1880, says that Sydney Ringer received this remedy from a Mr. Ryder, who brought it from the Fiji Archipelago, stating that a certain European, who had married the daughter of a chief, had learned the secret from his father-in-law, in whose family it had been an heirloom for some two hundred years—the old story, with slight variations, so often told before, of drugs our knowledge of which first came from the missionaries. This first sample of tonga was subjected to a chemical analysis by Gerrard (*Pharm. Journ. and Trans.*, 1880, p. 849), the sole one as yet reported. The fibres contain a volatile alkaloid, to which possibly it owes its virtues, such as they are, and which for the present we may call "tongin." The most important parts of the bark are, pectin, glucose, a little ethereal oil and fat.

Tonga has not been able to firmly establish itself in Germany as an anti-neuralgic remedy. The *Pharmaceutische Centralb.*, of December, 1881, says that this much-lauded medicine had even then become nearly forgotten in that country. In reply to this *The Therapeutic Gazette*, 1882, p. 40, says, rather mischievously, that the German faculties cannot be blamed for declining to handle a drug of the composition of which they know but little, if anything. Faculties are certainly not noted for experimenting with drugs of this nature, but should it appear that the drug under consideration has merit, we may entertain the certain hope that this obstacle to its full investigation will be overcome in due season.

GINGER BEER PLANT.†

BY W. G. SMITH.

The Editor of the *Gardeners' Chronicle* has several times been requisitioned by correspondents (mostly anonymous) for a scientific description of the "Ginger Beer Plant." The correspondents want to know its botanical name and native country. The writer of this note has also been tormented weekly, almost daily, on the same subject for two or three years. Every one has been asking him for the "regular Latin or Greek name" of the "Ginger Beer Plant." Benevolent old ladies, clergymen and officers of the Blue Ribbon Army, have called upon him, or written for a scientific explanation, hoping to make the "Ginger Beer Plant" a boon to the poor. One person wished to feed paupers with it; another hoped by its means to knock all the publicans on the head; a third to send it in barrels for the army in the Soudan. When such persons have been told it is merely a form of German yeast they have turned away disappointed and disgusted. Something more must evidently be done for this rum shrub, of which I have recently had application for slips, rooted cuttings and seeds.

The last letter sent to the *Gardeners' Chronicle* was to this effect:—"I cannot learn anything more about it than that it is an American plant. Cannot find out where it is procured—only how to make it. Empty the contents of the small bottle into the wine-bottle. Bruise about half an ounce of ginger, two tablespoonfuls of white sugar, put in a jug, pour boiling water over it, let it stand till nearly cold, then put the plant in the bottle of ginger, sugar, and water. Cork it tight, and when it begins to ferment the cork will fly out. The plant will grow if fed every day, and soon be enough for two bottles. It is best to empty it once a week into a pan and wash it with cold water, then put it in the bottle again."

To the unaided eye the Ginger Beer Plant looks like a lump of paste, and when placed under the microscope it is seen to consist of more than one of the yeast fungi, in a mucilaginous medium. It belongs to the group of fungi termed Saccharomyces, of which there are many species, the one used for beer being *S. cerevisiæ*. Mr. Berkeley, Mr. Hoffmann, Mr. Huxley, and many other gentlemen, British and foreign, have written about yeast in its different forms and conditions.

The "Ginger Beer Plant," like all other yeast fungi, excites fermentation in sweet solutions and sets free carbonic acid gas.

As all the correspondents insist on this "American plant" being a new species I propose to humour them by calling it *Zingibeerophora spumacephala*!.

* The name "Tonga" had previously been applied to a narcotic extract (see *Pharm. Centralb.*, 1881, page 100) derived from *Datura sanguinea*, R. and P.

† From the *Gardeners' Chronicle*.

LIVAROT CHEESE.*

One of the most popular cheeses in France, and one which is not only profitable in its manufacture but well adapted to our dairy farmers, is the Livarot, and the following is the description given of it by Mr. Long in one of his South Kensington lectures:—The cheese takes its name from the town of Livarot in the department of Calvados, which is the principal centre of its manufacture. To the workmen it is almost indispensable. The milk taken from the cow is creamed on the following day, and poured into large wooden tubs holding about fifty gallons, being then brought to the temperature which it possessed on leaving the cow. The rennet is then added—in summer one, and in winter two dessert-spoonfuls being required for six gallons of milk (as a rule this rennet is made on the premises, several calves' stomachs being cured together),—and for each a large spoonful of salt and three glasses of water are added. In one or two hours the coagulation is complete, when the curd is broken up and laid upon rushes or a clean cloth. Before placing in the moulds it is indispensable that the curd should be reduced to small cubes no larger than lumps of sugar. The curd is placed in the circular wooden moulds after having been left to drain for a quarter of an hour. In these moulds it completely drains and attains a proper consistence. This result can be obtained in three or four hours when it is warmed, but the quality of the cheese will be impaired, and it must not be left too long in the moulds—one to four days, according to the season of the year and the temperature. The moulds are turned over one hour after the curd has been placed in them, this operation being repeated half a dozen times before the cheeses are released. The cheeses are salted with the hand, and left for four or five days on inclined wood or stone tables, and then taken to the *hâloir* or market. The *hâloir* is an apartment with windows let into opposite walls, through which a current of air passes for the purpose of desiccating the cheeses placed in various stages upon lath racks, which have been previously covered with straw. The cheeses are left in this place for fifteen to thirty days, and then taken to the cave, all the apertures of which are closed and a uniform temperature kept. In consequence of the gas given off from the cheese the walls are not made of brick or stone, but of mortar mixed with chopped hay. The cheeses, placed on planks, are turned twice weekly in winter, and three times weekly in summer, being slightly wetted each time with pure water, and salted afresh where necessary. At the end of eight or ten days in the cave they are placed on their edges on a species of sedge to assist the process of drying. They remain in the cave for three to six months, according to their size, and when packed for transmission to market are coloured with annatto. It requires about five pints of milk to make a cheese, September and October being the months chosen in which to make them. Several manufacturers of these cheeses make from 5000 to 8000 dozen in a season.

CHEMISTS' ASSISTANTS IN FRANCE.

For some past a Parliamentary Commission, appointed by the French Chamber of Deputies, has been engaged in an investigation as to the causes which have led to the present industrial crisis in France and increased the number of the unemployed. In the course of the inquiry the Commission has taken the evidence of representatives of various callings, and amongst others of the officials of the Chambre Syndicale des Elèves en Pharmacie. By the courtesy of a correspondent we have been supplied with a copy of the evidence of the President of this Association, M. Parisot, and as an extremely intelligent statement of the condition of a large class of pharmacists' assistants in France, as well as an expression of the views of his *confrères* as to the causes that have contributed to the disadvantages under which they consider they labour and the methods available for their alleviation, it naturally proves to be very interesting. The evidence consists partly of a written reply to what appears to have been a series of printed interrogatories addressed to the Association in common with other similar bodies, and partly of a supplementary *vivâ voce* statement which M. Parisot was allowed to make before the Commission.

M. Parisot premises that the general industrial crisis in France affects pharmacy as it does all other callings, but he expresses the surprise with which he has observed, in following the evidence given before the Commission, that all the callings officially represented were better remunerated than pharmacy, whilst they had fewer hours of labour. He estimates that the three thousand *élèves en pharmacie* in Paris receive on an average, when neither boarded nor lodged, 190 francs per month. For this they serve, on an average, fifteen hours a day, besides being liable to night duty, for which they receive no extra pay. It will be remembered by those who have read Mr. Möller's interesting account of modern pharmaceutical study,* that in France the pharmaceutical student, after passing the required examination in the "classical" schools, has to serve three years in a pharmacy, after which, if he is in a position to do so, he proceeds to the three years' course in a school of pharmacy and the obtaining of a diploma. But it appears that in a considerable number of cases the pupil, from want of means or for other reasons, does not go on at once for a diploma and as he is still only an *élève* he obtains no amelioration of his position while acting as an assistant, notwithstanding his increased practical experience. It is estimated by M. Parisot that in Paris there are from one hundred and twenty to one hundred and fifty *élèves* unoccupied and about two hundred who have been compelled to accept situations of much lower value than they are capable of filling. But it was admitted that the number of *élèves* not in a situation is affected by the fact that some of them necessarily leave their employment to attend the courses of lectures.

When we come to the causes to which the *élèves* attribute what they consider to be their present unsatisfactory condition, it is pleasant to find that there is no disposition manifested to raise trivial complaints against the employers as a class, but rather to find an explanation in circumstances that are unfavourable alike to employers and employed. It is worthy of note also that some of these circumstances are similar to those that have largely affected chemists and druggists in this country. During the last ten years, M. Parisot says, the pharmacies in Paris have increased in number and decreased in value. Some of the new comers, in order to attract a connection, have sold specialties at a discount sometimes amounting to 25 per cent. Besides this, the hours during which pharmacies are kept open have been augmented, so that whereas before 1870 most of these establishments were not opened before half-past seven in the morning and were closed at half-past nine at night, they are at present opened at seven in the morning and are not closed until eleven at night. Nevertheless, M. Parisot said he could refer to a dozen houses, which, although they have been conducted with the greatest care, have decreased in value during this time by two-thirds. So far as the *élèves* are concerned they appear to look for an improvement in their position in some enlargement of the field in which they may seek employment. The desire expressed to the Commission in their name is that a diploma of "chemist" should be instituted, which would allow *élèves* who do not possess the means for the purchase of pharmacies to enter manufactories of chemical products and other works as foremen, or in any other capacity in which their special knowledge and training could be utilized. To some onlookers this will appear like placing an unwarranted amount of faith in a name, for it is not quite clear why an *élève* who possesses capacity for such an appointment should not take one, if available, without waiting for a diploma. Another portion of the evidence, which, we confess, appears to us rather puerile, is that wherein a part of the depression under which *élèves en pharmacie* suffer is attributed indirectly to the unfair com-

* See *Pharmaceutical Journal*, [3], xii., 397.

petition of German chemical manufacturers. If it be true that certain products are regularly purchased in France and sent to Germany for manipulation, to be afterwards re-imported into France at a price 20 per cent. below their original cost, there might be reasonable ground for suspecting a fraud, but it would be a fraud that French chemists should be competent to detect and protect themselves from. Moreover, one of the cases mentioned as an illustration of the dishonesty of the foreign manufacturer,—that of the sophisticated quinine supplied to the hospitals,—appears to be singularly unfortunate, since, unless we are mistaken, the fraud was traced to the French contractor, who was convicted of the offence and sentenced to a term of imprisonment that has hardly yet expired.

THE USE OF METHYLATED SPIRIT IN MANUFACTURES.

The arrangement, based upon the experiments made by Professors Graham, Hofmann, and Redwood, under which persons carrying on in this country manufacturing industries involving the use of spirit of wine have now for nearly thirty years been exempted from the payment of duty upon the spirit they use, if it be previously mixed with methylic alcohol in certain proportions, has been such a decided boon that the withdrawal of it could hardly be contemplated with equanimity. In the United States, however, manufacturers have since the war of secession been under the disadvantage of using spirit upon which they have had to pay a tax equal to five or six times its actual original value. For various reasons the plan adopted in this country has been deemed impracticable there; probably one of the most forcible being that as at least one-half of the whole spirit revenue has been derived from alcohol used for manufacturing purposes the consequent loss seemed to be too great to incur. But the prosperity consequent upon peace has encouraged American financiers to contemplate even this eventuality, and for the last year or two the subject has been under the consideration of the Congress. Indeed, the question just now appears rather to lie between permitting the use of methylated spirit duty free and the abolition of the spirit duty in the United States altogether. Obviously either of these steps would be of vast importance to chemical manufacturers, and it is not surprising to find one so eminent as Dr. Squibb discussing the *pros* and *cons* of the question. In doing so he refers to some of the disadvantages attending the adoption of the artifice of methylating as a means of preventing fraud on the revenue, and he evidently uses them to enforce the argument for a total abolition of the duty. Fortunately or unfortunately, this latter course does not come within the range of the probabilities in British finance; nevertheless some of the points mentioned by Dr. Squibb have an important bearing upon the conditions under which manufacturers are allowed to use duty-free spirit in this country.

Referring to a Bill which has been introduced into the House of Representatives, having for its object to exempt from duty any spirit to which a definite percentage of methyl alcohol has been added, Dr. Squibb points out that it appears to be based upon the theory that methyl alcohol once added to clean spirit spoils it permanently and irrecoverably for drinking purposes. This, of course, is a fallacy, for it has long been known, as Dr. Squibb points out, that the methyl alcohol can be taken out with comparative ease, and that obstacles to the cleaning of methylated spirit so as to render it capable of being used as a beverage are dependent rather upon the honesty or fears of the manufacturer than upon any inherent difficulty in the operation. Indeed, the possibility of cleaning methylated spirit is recognized in the fact that the law forbids it to be done. In this country it is believed that the law-abiding spirit, confirmed perhaps by the vigilance of the Excise authorities, is sufficient practically to secure obedience to such a prohibition. But Dr. Squibb has evidently strong misgivings as to whether such an end can be attained in the United States, for he believes that many manufacturers would buy the methylated spirit, clean it sufficiently for their purposes at an expense of a few cents a gallon and take the risk of detection and a penalty following. To use his own words, "With a not uncommon disregard for law and indifference to crime, and with sufficient cunning and care, such practices could be easily carried on to any extent, and so long as the cleaned spirit was used strictly for arts and manufactures it would be argued that the intent of the law would be fulfilled and no harm done." But in view of the fact that spirit of wine containing the full proportion of methylic alcohol is utterly inapplicable for many purposes in the arts and manufactures, such practices would interfere with the business of honest manufacturers and tend to diminish their profits, because they would have to compete in business with less scrupulous opponents.

So far the questions raised by Dr. Squibb, although of indirect interest to other countries, affect principally the citizens of the United States, who are quite competent to decide them without obtrusive advice. But it will be evident that their decision may exercise a far-reaching influence upon the manufacture of chemicals throughout the world. Doubtless American manufacturers have for several years past been heavily handicapped in their operations, as compared with continental European manufacturers, who have had an untrammeled supply of duty-free spirit, or even with British manufacturers working under some restriction. This disadvantage has been so great, that notwithstanding the high existing protective duties it has been possible sometimes to beat Americans out of their own markets. But it will hardly be consistent with the reputation of United States enterprise if such a condition of affairs survives either a partial or a total abolition of the spirit duty; indeed we should rather expect to find that the European manufacturers are encountering fresh and vigorous rivals in the other markets of the world.

At the annual meeting of the Pharmaceutical Society of Victoria last month it was resolved to take advantage of the passing of a "Companies' Statute" recently, "for the registration of scientific and literary associations and societies," to incorporate and register the Society under the title of the "Pharmaceutical Society of Australasia." In virtue of this registration the Society will become a body corporate, with perpetual succession, just as if it were incorporated by Royal Charter or by an Act of Parliament, and will be able to hold property in its own name without the intervention of trustees. Speaking upon this subject in his annual address, and evidently referring to the more inclusive range of the new title, the President expressed an opinion that under the new constitution, with its wide scope, there was no reason why the Society should not, in a few years, occupy a position as high and important as that of the Pharmaceutical Society of Great Britain. We hope the anticipation may be verified.

* * *

A few weeks ago we mentioned (before, p. 675) that the New Zealand Government had issued an Order in Council requiring that every retail sale of strychnia or arsenic should be preceded by the production by the purchaser of a statutory declaration as to the purpose for which the poison was required, and that a meeting of pharmacists to discuss the subject was to be held in Dunedin. We learn now that as the result of a representation by the Pharmacy Board the Order has since been withdrawn. When the fact was brought under the cognizance of the colonial Premier that as a consequence of the Order the payment of half-a-crown stamp duty and the services of a justice of the peace had become the indispensable preliminaries to the purchase of a shillingsworth of poison the absurdity of the position was admitted and the obnoxious order cancelled.

* * *

We have received a copy of the first part of a new quarterly journal, entitled 'Drugs and Medicines of North America,' which is to be "devoted to the historical and scientific discussion of the botany, pharmacy, chemistry and therapeutics of the medicinal plants of North America, their constituents, products and sophistications," and will be conducted by Messrs. J. U. and C. G. Lloyd, of Cincinnati. The plants treated of in this part are *Clematis virginiana*, *Thalictrum dioicum*, *Thalictrum anemonoides*, *Anemone nemorosa* and *Anemone patens*, all Ranunculaceous plants, from which it would appear that there is an intention to proceed by natural orders. The work is freely illustrated with well-executed uncoloured drawings of the plants and parts of them, as well as diagrams showing their microscopical structure, and bids fair to be a most valuable addition to the literature of the materia medica.

* * *

In reviewing the subject of pulsatilla, Messrs. Lloyd state that the United States *Anemone patens*, var. *Nuttalliana*, is so nearly like the foreign allied species that there is no reason why the future supply of the drug for that country should not be derived from the native plant, especially as the European species collected for medicinal use differ from each other as widely as from the variety of the species indigenous to America.

* * *

The new number of *The Asclepiad* contains a variety of interesting articles, and among them a paper, by Dr. Richardson, on John Keats, who is claimed as "an Esculapian poet." The paper is illustrated by a beautifully executed portrait of the poet in his twenty-third year, the original picture from which it is taken being in the possession of Mr. Buxton Forman.

* * *

In a paper recently read before the Hygienic Society of Berlin, Herr Miller reported the results of his endeavours to determine the nature of the ferment occurring in the mouth to which he is disposed to attribute the setting up of caries in the teeth. He stated that he had found the ferment to exist in the saliva and that it appeared to result from the growth of two forms of lactic acid fungi, which may prove to be reducible to a single species. In comparative tests as to the agents best suited to stop the development of the organisms and the consequent formation in the mouth of acid, to the action of which on the enamel of the teeth he considers the caries to be due, he found that a solution of corrosive sublimate, 1 in 500,000, checked the formation of acid, and a solution of 1 in 100,000, completely destroyed the organisms. He therefore thinks that a solution of corrosive sublimate, not strong enough to be dangerous, would be found a very effective mouth wash. The spores of the organisms were found to remain capable of development after an hour's boiling in a solution of meat extract. The organisms were also destroyed by solution of potassium permanganate, 1 in 1000; solution of carbolic acid, 1 in 500, and salicylic acid, 1 in 125, whilst the development of acid was checked by solutions of half these strengths.

* * *

The tariff law of the United States has provided still another nut for the superior officials to crack. A dispute appears to have arisen in respect to the essential oil of bitter almonds, which the importers claim to be covered by the term "almond oil," and therefore to be on the free list, whilst the custom house "appraiser" holds that it is liable to pay an import duty of 25 per cent. as an essential oil.

* * *

The next meeting of the Society of Chemical Industry will be held on Monday next, May 5, at 8 p.m., in the Chemical Society's Rooms, Burlington House. The papers to be read are: "On the Composition and Illuminating Power of Coal Gas," by Dr. Percy Frankland; and "On the Estimation of the Illuminating Power of Gas Burners, especially those of large size," by Mr. W. J. Dibdin.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, May 7, at 9 p.m., when a paper on "Tartar Emetic" will be read by Mr. C. Thompson.

EXAMINATIONS IN LONDON.

April 16, 17, 18, 23, 24 *and* 25, 1884.

Present on the 16th, 17th and 18th—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Present on the 23rd and 24th—Mr. Carteighe, President; Mr. Atkins, VicePresident; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Present on the 25th—Mr. Carteighe, President; Mr. Atkins, VicePresident; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on the 17th, 18th, 23rd, 24th and 25th, on behalf of the Privy Council.

MAJOR EXAMINATION.

16*th.*—*Eight* candidates were examined. *Three* failed. The undermentioned *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Ashton, Frederick William .. Market Harborough.
Cule, Taliesin ....Merthyr Tydvil.
Dobson, George Turner ....Holsworthy.
Granger, Harold ....Nottingham.
Neve, Annie ....London.

23*rd.*—*Seven* candidates were examined. *One* failed. The undermentioned *six* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Jones, Morgan Isaac ....Aberdare.
Luxmoore, Charles Mann ....Bristol.
Marshall, Sam ....Hyde.
Milford, James Emery ....Bath.
Spilsbury, James .... Stafford.
Wood, John ....Leighton Buzzard.

MINOR EXAMINATION.

16*th.*—*Twenty-one* candidates were examined. *Fifteen* failed. The undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Atherton, Henry Charles ....Tunbridge Wells.
Atkinson, William George ....Ulverston.
Blyton, Thomas Bage ....Manchester.
Burgess, Thomas ....Liverpool.
Callaway, George Frederic.......Ipswich.
Dunn, George Marchant..........London.

17*th.*—*Twenty-seven* candidates were examined. *Eighteen* failed. The undermentioned *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Carter, Benjamin........ ....Falmouth.
Chifney, George Pearmain ....Mildenhall.
Deck, Arthur Albert ....Cambridge.
Dunn, Isaac George................Chard.
Eastes, Ernest John................Deal.
Edgar, Frederick George..........Southsea.
Evans, Daniel Thomas ....Llandyssul.
Fowle, Sydney ....London.
French, Herman ....Milton next Gravesend.

18*th.*—*Twenty-six* candidates were examined. *Fifteen* failed. The undermentioned *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Freshney, John Wm. Septimus.Lincoln.
Golding, Frank Oliver... ....London.
Groves, Thomas ....Bridport.
Hacon, Elizabeth Constance ...London.
Hall, Reuben ....Bath.
Hallawell, Joseph Lefebore ...Ayr.
Hare, George Edward............Nottingham.
Harrison, Thomas ....Birmingham.
Hickley, Arthur Mackenzie ...London.
Hodgson, George ....Doncaster.
Hudson, Thomas Herbert ......Leeds.

23*rd.*—*Twenty-two* candidates were examined. *Fifteen* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jenkins, Thomas ....Aberdare.
Lewis, Thomas ....Llagain.
McDiarmid, Fraser ....Deal.
Madge, Thomas William ......Shaldon.
Marlar, John Frederick ....Halstead.
Mathias, James Russell Hy. ...Tenby.
Smith, Albert ....Stalybridge.

24*th.*—*Twenty-five* candidates were examined. *Sixteen* failed. The undermentioned *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Moss, Thomas Abbot ....Carlisle.
Owen, John ....Sheffield.
Paul, Ernest ....Windsor.
Pierce, Robert Wynne Charles.Bangor.
Ridley, Henry ....Ipswich.
Roberts, Robert ....Llangynidr.
Russell, Harry Edward ....London.
Smith, Joseph De Carle ....Norwich.
Taylor, John Williams ....Norwich.

25*th.*—*Twenty-five* candidates were examined. *Fifteen* failed. The undermentioned *ten* passed, and were declared qualified to be registered as Chemists and Druggist:—

Scholes, William Isaac ....Pendleton.
Skoulding, William George ...Oakham.
Spurway, Edgar ... .Kidderminster.
Stewart, Robert McAll ....Penryn.
Sutcliffe, John Arthur............Halifax.
Tennant, Alfred ....Lancaster.
Timbury, Alfred Jeffries.........Leominster.
Tugwell, Ernest Harry ....Greenwich.
Verdon, Levinons ....Knighton.
Worfolk, Alfred Egbert ....Knottingley.

MODIFIED EXAMINATION.

16*th.*—*One* candidate was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Bassett, John ....Leominster.

PRELIMINARY EXAMINATION.

25*th.*—The undermentioned certificates were received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Allin, Charles James ....St. Albans.

Certificate of the University of Aberdeen.

Farquharson, Alex. McDonald.Aberdeen.

Certificates of the University of Cambridge.

Emery, Alfred ....London.
Fuge, Harry Dixon ....Matlock Bath.
Minter, Albert Edward ....Balham.

Certificate of the University of London.

Barclay, John ....Birmingham.

Certificates of the University of Oxford.

Roberts, Thomas ....Llanfyllin.
Stubbs, Frederick..................Birkenhead.
Wynne, William Arthur.........Mold.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting was held in the Institute Room, Shakespeare Street, on Friday evening, April 25. In the unavoidable absence of the President, through illness, the chair was occupied by Mr. Wilford, Vice-President.

There was hardly such a good attendance as usual.

The Secretary, Mr. C. A. Bolton, read the reports received from Professor Clowes, D.Sc., F.I.C., of the Pharmaceutical Chemistry Class, held at the University during the past winter; it was of a most satisfactory character, 50 per cent. of the candidates who presented themselves for examination having succeeded in satisfying the examiner.

Mr. Major, B.A., F.R.G.S., B.Sc., then delivered a most instructive and interesting lecture upon "Epidemics." An epidemic was defined as a disease attacking a large number of people and being spread by infection. It was distinguished from an endemic by the latter being confined to one place, as the malaria around Rome and the leprosy of the Sandwich Islands. Epidemics are produced by germs, the largest of which are not more than $\frac{1}{6000}$th of an inch in diameter. The difference of philosophers as to the source of these germs was mentioned. On the one side, Pasteur, Huxley and Tyndall, hold that they must be produced by pre-existing life; the other side (Bastian and others), that they may be produced from inorganic substances; the experiments by which they arrived at their conclusions being pointed out and explained. The lecturer then alluded to the folly of people being careless of catching such diseases as scarlatina on the grounds "we shall have to take it some time and the sooner the better." Nothing could be more erroneous or misleading, as less than 50 per cent. of the population ever have these diseases at all and the greatest fatality is amongst young children from one to five years old, for this reason, these germs attack the mucous membrane and this, in children, is very delicate and most susceptible to their influence. Consumption was treated of and the new remedies of inhalation recently brought into prominence by the faculty explained. It was also remarked that consumption occurred much less on mountain tops and at the sea side, on account of the large amount of ozone present in the atmosphere. Statistics were alluded to to show that consumption increases with the density of population per square mile. Methods of propagating the disease were treated in detail. Garments and woollen fabrics so very often proving means of carrying the germs from one part to another, reason urged that the safest and best course was to destroy them. The lecturer then gave some most potent arguments in favour of cremation, urging that quick decay was much better than the present slower one. The reason why milk is such a very suitable medium for carrying disease germs was explained to arise from the fact that it is of such a character as to be one best suited for increasing the number of germs to a rapidly alarming extent as well as at the same time increasing their activity.

A most cordial vote of thanks was passed to the lecturer on the motion of Mr. W. H. Parker, seconded by Mr. A. Middleton.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Some New Optical Instruments and their Arrangements.

On Monday, the 28th ult., the first of two Cantor lectures upon "Some New Optical Instruments and their Arrangements" was delivered by Mr. J. Norman Lockyer. He commenced the lecture by stating three rather startling facts: that there is at present no manufactory of optical glass in England; that, as far as he knows, there is only one such manufactory in the world; and that it will most probably be closed within a period of six months. Two centuries ago it was considered almost impossible to construct a telescope for the purpose of taking astronomical observations, owing to the great focal length of the lens; the minimum focal length being about 100 feet, the expense of mounting must have been enormous. Hooke had avoided the necessity of shifting the telescope in order to obtain views of different celestial bodies, by the construction of a movable mirror, with which light could be thrown into the telescope from any point in the heavens; this idea, however, remained dormant till 1869. Two discoveries about that time led to its application. Liebig found that it was possible to add a film of silver to the polished surface of glass, by means of the admixture of two solutions, one consisting of nitrate of silver and ammonia, the other of nitrate of silver and Rochelle salt; Fougot at the same time was able to construct a perfect optical plane on geometric principles. During the lecture Mr. Norman Lockyer remarked upon the custom of opticians making mirrors thin, as being less affected by temperature. He was himself of opinion that the thickness of small mirrors should be about one-fifth of their diameter, but should be reduced to one-seventh when of a large size. As to weight he considered that a mirror of 5 feet in diameter and one-seventh the thickness should weigh about a ton. Remarking that up to the present no means had been contrived to enable telescopic observations of the stars to be taken with comfort, and at the same time allow of a view of every part of the sky, the lecturer mentioned that two movable domes are in the course of construction in Paris with this object, the larger one having a diameter of rather over 60 feet. They are hemispherical in shape, and the principal material used in their construction steel. The machinery is so arranged as to allow not only the dome and telescope, but also the observer's chair to move in unison; a circular rim floating in a trough supports the whole dome, and so slight is the friction that it may be easily turned by a child. The liquid used as the floating medium consists of a solution of magnesium chloride of a certain density, which freezes at $-35°$ C., and does not attack the galvanized iron of which the trough and rim are constructed. Should this floating system fail the dome would only fall 1 or 2 millimetres and would then be worked by an ordinary circular railway. The great drawback to this arrangement is the expense of the structure of the dome, which amounts to three times that of the telescope. The lecturer himself favoured an instrument invented by M. Laville, which he considered gave better results. This instrument mainly consists of a telescope, bent about the middle at an angle of 90°, the light being reflected by a mirror placed in the right angle; another movable mirror, at the extreme end of the telescope, enables observations to be taken of stars in different meridians, whilst the telescope can itself be moved to obtain views of the equatorial stars, thus ensuring views of all parts of the sky without the necessity for a "finder." An objection has been raised to this instrument on account of the loss of light arising from the double reflection of the mirrors, and consequently a loss of definite view, but Mr. Lockyer states that this loss, if at all appreciable, could be remedied by a slight enlargement of the aperture

Parliamentary and Law Proceedings.

The Ontario Pharmacy Act, 1884.

ASSENTED TO MARCH 25, 1884.

Her Majesty, by and with the advice and consent of the Legislative Assembly of the Province of Ontario, enacts as follows:—

1. This Act may be cited as "The Pharmacy Act, 1884."

2. The Ontario College of Pharmacy, incorporated by the Act passed in the thirty-fourth year of Her Majesty's reign, and chaptered 34, is hereby continued.

3. The Ontario College of Pharmacy shall have power to acquire and hold real estate, not exceeding at any time in annual value five thousand dollars, and the same, or any part thereof, may alienate, exchange, mortgage, lease, or otherwise charge or dispose of as occasion may require, and may erect buildings for the purpose of accommodating lecturers on chemistry or pharmacy, or for a library, pharmaceutical museum, or specimen room for the use of the members and associates of said College; and all fees payable under this Act shall belong to the said College for the purposes of this Act.

Pharmaceutical Council.

4. There shall be a Council of said College, to be called the Pharmaceutical Council, which shall consist of thirteen members, who shall be elected as hereinafter provided, and shall hold office for two years, and the said Council shall, subject to the laws thereof, have sole control of the real and personal property of the College, and have authority to grant certificates of competency to conduct the business of a chemist or druggist, and to be registered subject to the provisions of this Act.

5. Any member of said Council may at any time resign by letter directed to the registrar of said College: and in the event of any vacancy occurring, the remaining members of the Council shall fill up such vacancy from the members of the College.

6. An election of members of the said Council shall be held on the first Wednesday in July in every second year, and the persons qualified to vote at such election, shall be such persons as are members of the said College.

7. The Council shall, at their first meeting, elect from among themselves a president and vice-president, and shall appoint a registrar and such other officers as the said Council may consider necessary.

Certificates of Competency.

8. The said Council shall hold at least two sittings in every year, on the first Wednesday in February and first Wednesday in August, for the purpose of granting certificates of competency, at such places as they may by resolution appoint, of which due notice shall be given for at least one month in the *Ontario Gazette*, and at least two newspapers in the City of Toronto.

9. The Council of the said College shall, subject to the supervision and disallowance thereof by the Lieutenant-Governor in Council, have authority to prescribe the subjects upon which candidates for certificates of competency shall be examined, to establish a scale of fees not to exceed 10 dollars, to be paid by persons applying for examination; and to make bye-laws, rules and orders for the regulation of their own meetings and proceedings, and those of the College; and for the remuneration and appointment of examiners and officers of the said College; and for the payment of remuneration or indemnity to the members of the said Council in attending its sittings, or in attending upon the business of the said College; and in respect to any other matters which may be requisite for the carrying out of this Act; provided always, that no more than 5 cents per mile for travelling expenses, or more than 4 dollars per day for such days only as he shall be in actual attendance upon the business of the College, including going to and returning from such sitting, be allowed to any member for such expenses and remuneration.

10. The examinations of the College may be conducted by the members of the Council, or by persons appointed by them.

Who may apply for Certificates.

11. Subject to the rules, regulations and bye-laws of the Ontario College of Pharmacy, the following persons and no others may be admitted as candidates for certificates of competency:

(*a*) Any person who shall furnish to the Council of the said College satisfactory evidence of having, in pursuance of a binding contract in writing for that purpose, served as an apprentice to a regularly qualified pharmaceutical chemist for a term of not less than three years.

(*b*) In case any person who has apprenticed himself as aforesaid, shall by reason of the death, failure in business, or removal of his employer, or from any other cause satisfactory to the said Council, be unable to complete his apprenticeship with such employer, such person shall be at liberty, when and as often as this may happen, to enter into a new contract to complete the remainder of his unfulfilled term with any other regularly qualified pharmaceutical chemist.

(*c*) Nothing in this section shall apply to any person who had, prior to the passing of this Act, begun his apprenticeship with a regularly qualified pharmaceutical chemist without such binding contract in writing.

Preliminary Examinations.

12. Every person who may hereafter be desirous of becoming apprenticed as aforesaid, shall, before the term of his apprenticeship begins to run for the purpose of this Act, furnish to the registrar of the College a certificate or other evidence satisfactory to the Council, showing that prior to the commencement of such apprenticeship he had passed an examination entitling him to admission to a high school, college, collegiate institute, or to the fourth form of a public school for the Province of Ontario; provided that apprentices who have commenced their apprenticeship out of the Province shall give satisfactory evidence of having had equal qualifications to the aforesaid at the time when their apprenticeship was entered upon.

Registration.

13. It shall be the duty of the registrar to make and keep a correct register, in accordance with the provisions of this Act, as shown in schedule "B," of all persons who may be entitled to be registered under this Act, and to enter opposite the names of all registered persons who have died, a statement of such fact, and from time to time to make the necessary alterations in the addresses of persons registered under this Act, and shall cause to be printed and published on or before the fifteenth day of June of each year, an alphabetical list of the members who were on the first day of June of that year entitled to keep open shop as pharmaceutical chemists.

14. Any person having passed such examination as aforesaid to the satisfaction of the Council, shall be entered upon the roll of registered chemists and druggists and shall become a member of the College.

15. All persons who, on the fifteenth day of February, 1871, were in business as chemists and druggists, or chemists, druggists, or apothecaries, upon their own account, or in partnership with any other person, or who had before said day served an apprenticeship of three years, and acted as a druggist's assistant for one year, shall be entitled to be registered under this Act, upon production to the registrar of such evidence of their having been so engaged, as the Council of the said College may require, and upon payment of a registration fee of 10 dollars; provided, that applications for such registration be made within twelve months from the passing of this Act.

16. No name shall be entered in the register except of persons authorized by this Act to be registered, nor

unless the registrar is satisfied by proper evidence that the person claiming is entitled to be registered; and any appeal from the decision of the registrar may be decided by the Council of the said College, and any entry proved to the satisfaction of the Council to have been fraudulently or incorrectly made, may be erased from or amended in the register by order of the Council.

17. Upon any person being registered under this Act, he shall be entitled to receive a certificate in the form of schedule "D" or to the like effect, under the corporate seal of the said College, and signed by the registrar.

18. There shall be payable to the registrar of the said College, for the uses of the College, on the first day of May of each year, by every person registered and carrying on business as a pharmaceutical chemist, the sum of 4 dollars; provided that in case such person shall carry on such business in more than one locality, the further sum of 4 dollars shall be payable by him, as aforesaid, for each such additional place of business, and provided also, that all employees or assistants who manage or have charge of such additional places of business, shall be legally qualified pharmaceutical chemists.

19. Any person registered under this Act, and no other person, shall be entitled to be called a pharmaceutical chemist, and no other person except a pharmaceutical chemist, as aforesaid, or his employee or employees, shall be authorized to compound prescriptions of legally authorized medical practitioners; but no person shall be entitled to any of the privileges of a pharmaceutical chemist, or member of the said College, who is in default in respect to any fees payable by him by virtue of this Act.

20. Upon a resolution of the Council of the said College being passed, declaring that any person in consequence of his conviction for any offence or offences against this Act, is, in the opinion of the Council, unfit to be on the register under this Act, the Lieutenant-Governor in Council may direct that the name of such person shall be erased from such register, and it shall be the duty of the registrar to erase the same accordingly.

21. Every pharmaceutical chemist carrying on business on his own account shall display his certificate in a conspicuous position in his place of business.

22. Every person having been registered under this or any former Act, as a pharmaceutical chemist, shall, on retiring from business as such chemist, give the registrar notice in writing of the same, and in default thereof he shall remain liable for his annual registration fee; provided, that it shall be lawful for any such person to resume the business of chemist and druggist at any time after retiring therefrom as aforesaid, upon giving notice in writing to the registrar of the College of his intention so to do, and upon payment to him of the then current annual registration fee.

Preparation of Compounds.

23. All compounds named in the British Pharmacopœia shall be prepared according to the formula directed in the latest edition published "by authority" unless the College of Physicians and Surgeons of this Province select another standard, or unless the label distinctly shows that the compound is prepared according to another formula.

Sale of Poisons.

24. No person shall sell or keep open shop for retailing, dispensing, or compounding poisons, or sell or attempt to sell any of the articles mentioned in schedule "A" to this Act, or assume or use the title of "chemist and druggist," or "chemist," or "druggist," or "pharmacist," or "apothecary," or "dispensing chemist," or "druggist," in any part of the Province of Ontario, unless such person is registered under this Act, and unless such person has taken out a certificate under the provisions of section 18 of this Act, for the time during which he is selling or keeping open shop for retailing, dispensing, or compounding poisons, or assuming or using such title; provided, that nothing in this Act contained shall be taken to prevent the sale, by persons not registered in pursuance of this Act, of Paris green, London purple, and other arsenical insecticides, so long as such articles are sold in well secured packages distinctly labelled with the name and address of the seller and marked "Poison," and a record of such sales is kept as required under the provisions of this Act.

25. The several articles named or described in schedule "A," shall be deemed to be poisonous within the meaning of this Act, and the Council of the Ontario College of Pharmacy, hereinbefore mentioned, may from time to time by resolution declare, that any article in such resolution named ought to be deemed a poison within the meaning of this Act, and thereupon the said Council shall submit the same for the approval of the Lieutenant-Governor in Council, and if such approval is given, then such resolution and approval shall be advertised in the *Ontario Gazette*, and on the expiration of one month from such advertisement the article named in such resolution shall be deemed to be a poison within the meaning of this Act, and the same shall be subject to the provisions of this Act, or such of them as may be directed by the Lieutenant-Governor in Council.

26. No person shall sell any poison named in the first part of schedule "A" either by wholesale or retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained is distinctly labelled with the name of the article and the word "poison," and if sold by retail, then also with the name and address of the proprietor of the establishment in which such poison is sold; and no person shall sell any poison mentioned in the first part of schedule "A" to any person unknown to the seller unless introduced by some person known to the seller; and on every sale of any such article the person actually selling the same, shall, before delivery, make an entry in a book to be kept for that purpose, in the form set forth in schedule "C" to this Act, stating the date of the sale, the name and address of the purchaser, the name and quantity of the article sold, the purpose for which it is stated by the purchaser to be required, and the name of the person, if any, who introduced him, to which entry the signature of the purchaser shall be affixed.

Offences and Penalties.

27. No person shall wilfully or knowingly sell any article under the pretence that it is a particular drug or medicine which it is not in fact, and any person so doing (besides any other penalties to which he may be liable) shall be subject to the penalties prescribed by section 28 of this Act.

28. Any person transgressing any of the provisions of this Act, or selling any poison in violation thereof, shall for the first offence incur a penalty of 20 dollars and costs of prosecution, and for each offence committed subsequent to such conviction, a penalty of 50 dollars and costs of prosecution, to be recovered in a summary manner, before one or more justices of the peace or police magistrate, on the oath of one or more creditable witnesses, one moiety to belong to the prosecutor and the other to be paid to the registrar for the use of the College.

29. In any prosecution under this Act it shall be incumbent upon the defendant to prove that he is entitled to sell or keep open shop for compounding medicines or retailing poisons, and to assume the title of Chemist and Druggist, or other title mentioned in section 24 of this Act, and the production of a certificate purporting to be under the hand of the registrar and under the seal of the said College, showing that he is so entitled, shall be *primâ facie* evidence that he is so entitled.

30. No person selling articles in violation of the provisions of this Act shall recover any charges in respect thereof in any Court of Justice.

Act not to affect Medical Practitioners.

31. (1) Nothing in this Act contained shall extend to or interfere with the privileges conferred upon legally qualified medical practitioners by any of the Acts relating to the practice of medicine and surgery in this Province, and they may be registered as pharmaceutical chemists without undergoing examination; nor shall anything in this Act prevent any person whatsoever from selling goods of any kind to any person legally authorized to carry on the business of an apothecary, chemist and druggist, or the profession of a doctor of medicine, physician or surgeon, or veterinary surgeon, nor prevent the members of such professions supplying to their patients such medicine as they may require, nor interfere with the business of wholesale dealers in supplying poisons or other articles in the ordinary course of wholesale dealing.

(2) Nothing in this Act shall prevent any member of the College of Physicians and Surgeons of Ontario from engaging in and carrying on the business of an apothecary, chemist, or druggist without registration, under the provisions of this Act.

32. Upon the decease of any person legally authorized and actually carrying on the business of chemist and druggist at the time of his death, it shall be lawful for the executor, administrator or trustee of the estate of such person to continue such business if and so long only as such business is *bonâ fide* conducted by a pharmaceutical chemist registered under this Act, provided such executor, administrator or trustee continues to pay the annual registration fee of 4 dollars.

Honorary Members.

33. It shall be competent for the Council of the said College to elect as honorary members such persons as may be eminent for their scientific attainments; but such honorary members shall not as such be entitled to vote at elections or carry on the business of pharmaceutical chemists.

34. All persons approved of by the Council of the said College, who hold diplomas from the Pharmaceutical Society of Great Britain, or certificates from any pharmaceutical college in the Dominion of Canada or elsewhere, may be registered as members of the Ontario College of Pharmacy without the examination prescribed by this Act.

35. The Pharmacy Act, chapter 145 of the Revised Statutes of Ontario, is hereby repealed.

Schedule "A."

(*Secs.* 24, 25 *and* 26.)

PART I.

Acid, hydrocyanic (prussic).
Aconite and compounds thereof.
Antimony, tartrate of.
Arsenic, and all the compounds thereof.
Atropine.
Conia, and the compounds.
Corrosive sublimate.
Digitaline.
Ergot.
Hemp, Indian.
Morphia, and its salts and solutions.
Oil, cedar.
Strychnine, and nux vomica.
Savin and preparations of.
Varatria.

PART II.

Acid, oxalic.
Belladonna and the compounds thereof.
Beans, Calabar.
Cantharides.
Carbolic acid.
Chloral hydrate.
Chloroform and ether.
Conium, and the preparations thereof.
Croton oil and seeds.
Cyanide of potassium.
Euphorbium.
Elaterium.
Goulard's extract.
Hyoscyamus and preparations.
Hellebore.
Iodine.
Opium with its preparations, including laudanum, etc., but not paregoric.
Pink root.
Podophyllin.
Potassium, iodide of.
Potassium, bromide of.
St. Ignatius' beans.
Santonine.
Scammony.
Stramonium and preparations.
Valerian.
Verdigris.
Zinc, sulphate of.

Schedule "B."

(*Sec.* 13.)

Name.	Residence.	Qualification.	Remarks.
A.B.	Kingston.	In business for three years prior to Feb. 15, 1871.	Dead.
C.D.	Hamilton.	Examined and certified, July 12, 1871.	Erased by order of the Lieut.-Governor, dated October 14, 1875.
E.F.	London.	Served apprenticeship and as assistant.	

Schedule "C."

(*Sec.* 26.)

Date.	Name of purchaser.	Name and quantity of poison sold.	Purpose for which it is required.	Signature of purchaser.	Address of purchaser.	Name of person introducing purchaser.

Schedule "D."

(*Sec.* 17.)

I hereby certify that *C. D.* having first passed the examination prescribed by the Pharmaceutical Council, *or* having on the 15th day of February, 1871, been in business as Chemist and Druggist on his own account, *or* having, prior to the 15th day of February, 1871, served an apprenticeship of three years and acted as druggists' assistant for one year (*as the case may be*), was on the day of duly registered as a Pharmaceutical Chemist, and is authorized to carry on the business of Chemist and Druggist in the Province of Ontario, from the day of A.D. 18 to the day of

(Signed)

E. F.,

Registrar of the Ontario College of Pharmacy.

CRIMINAL POISONING WITH STRYCHNINE.

At the Newcastle Spring Assizes, on Saturday last, before Mr. Justice Hawkins, Sarah Jane Holmes was charged with feloniously killing and murdering John Holmes Burns. It appeared from the evidence that the prisoner had been living with a man called Burns, and during that time went under his name. The man having left her she seems to have enticed his little boy to her home and administered strychnine to him, taking some herself at the same time. The child died shortly afterwards. The following is the evidence given as to the purchase of poison by the prisoner:—

Robert Stobbs said he was a chemist carrying on business at 26, Sackville St., North Shields. On Mar. 1 the prisoner came to his shop and asked for a packet of vermin-killer. He asked her name, and she told him it was Mrs. Burns. She signed the book "Nance Burns, 38, Church Way." The vermin-killer was a powder he prepared himself. It contained strychnine, about 14 per cent. of the whole. The weight of the packet he sold her was 12 grains.

Cross-examined: She told him she wanted it for killing mice.

James Williamson said he was a chemist, and carried on business at 11, Union Street, North Shields. The prisoner came to his shop on March 25, last, and asked for a 6*d.* packet of Battle's vermin-killer, with which she was supplied. He made an entry of the sale in the poison book in the name and address of the prisoner, "Nance Burns, 38, Church Way." The packet was labelled "Poison." On the 17th ult. he supplied Detective John Riddell with a packet of the vermin killer, which was, externally, precisely the same as that sold to the prisoner.

Peter C. Reid said he was an apprentice to Mr. J. F. Hogg, chemist, Tyne Street. He remembered prisoner coming to the shop on April 1, and asking for a 6*d.* packet of Battle's vermin killer. On being supplied with a packet she signed the name "Nance Burns, 38, Church Way."

The prisoner was convicted and sentenced to death.

Obituary.

JOHN CHARLES BRAITHWAITE.

Many of our readers will learn with the regret due to personal acquaintance of the death at Twickenham, on Wednesday last, of Mr. John Charles Braithwaite, at the age of sixty years, after an illness lasting only a few days.

Mr. Braithwaite was born near Hereford, and served his apprenticeship to the General Apothecaries' Company of Liverpool, where he afterwards remained as assistant-chemist. He entered as a student in the School of Pharmacy, Bloomsbury Square, in the session 1847–48. He passed the Major examination in 1848, and afterwards succeeded to the post of demonstrator in the Society's laboratory, an office he discharged until 1860. After this he was, for a short time, chemist to the General Apothecaries' Company, of Berners Street, but in 1862 he gave up this post and devoted the whole of his time to teaching until the year 1877, when his failing health compelled him to relinquish this vocation. In consequence of this his means were much reduced, and this having become known to his friends he was nominated for election as an annuitant of the Benevolent Fund, and was elected in 1877.

Although no longer taking an active part in pharmacy Mr. Braithwaite's interest in the calling with which he had been so long connected continued, and the memory of the kindness he had received from many of his old pupils was preserved to the last.

Notice has also been received of the death of the following:—

On the 13th March, Mr. Samuel Kirkpatrick, Chemist and Druggist, East Reach, Taunton. Aged 56 years.

On the 5th April, Mr. James Edmunds, Chemist and Druggist, Newport, Mon. Aged 43 years.

On the 10th April, Mr. George Starke, Chemist and Druggist, Reading. Aged 78 years.

On the 14th April, Mr. William Eddie, Chemist and Druggist, Aberdeen, Aged 58 years.

On the 20th April, Mr. William Fleming Grayson Benson, Chemist and Druggist, Liverpool. Aged 55 years.

On the 20th April, Mr. Thomas Walton, Chemist and Druggist, Stanhope. Aged 62 years.

On the 21st April, Mr. William Henry Cuthbert, Chemist and Druggist, Willesden. Aged 54 years.

On the 23rd April, Mr. Robert Tully Watkins, Chemist and Druggist, Oxford. Aged 40 years.

On the 24th April, Mr. Joseph Bradley Shillcock, Pharmaceutical Chemist, Bromley. Aged 71 years. Mr. Shillcock had been a Member of the Pharmaceutical Society since 1842.

On the 26th April, Mr. Joseph Johnson, Chemist and Druggist, The Pavement, Merton. Aged 54 years. Mr. Johnson had been a Member of the Pharmaceutical Society since 1872.

On the 28th April, Mr. Edward Percival Guest, Pharmaceutical Chemist, Brentwood, Essex. Aged 56 years. Mr. Guest had been a Member of the Pharmaceutical Society since 1865.

Correspondence.

Spirit of Nitrous Ether.

Sir,—I observe a letter on the above subject from Mr. A. C. Abraham, which demands some notice, though its tone certainly cannot be commended. Passing over the preliminary sneer regarding "the source of these papers," and leaving Professor Hay and Mr. MacEwan to look after themselves, I shall refer to those points which more directly concern myself.

Now, I should at once express my sincere regret if I had misrepresented Mr. Abraham's views, but I do not find I have said anything meriting such a positive contradiction as he gives. Mr. Abraham's words are these—"He [Mr. Rimmington] forgets that acetates are *known* to do what he only suggests as a function of the nitrous acid and so fails to appreciate the value of the aldehyde, which we may fairly assume will be converted into acetic acid and afterwards into an acetate *when it reaches the blood*; where its action is required. I believe we have as much right to say that aldehyde is the active ingredient as to credit nitrite of ethyl with being such." This is just the opinion which I wish to condemn. Nitrites are powerfully diuretic; acetates are not; yet we are asked to believe that a minute amount of aldehyde may be the source of the physiological activity of spirit of nitrous ether. Mr. Abraham now believes that "the activity is probably due to some polymeric form of aldehyde, such as paraldehyde or some nitro compound of it." What grounds have we for such a supposition? The fact is, Mr. Abraham "believes" and "imagines" a great deal too much.

Regarding the next paragraph in Mr. Abraham's letter, I can only say that it is sheer nonsense, as there can be no doubt that acetic acid is absorbed into the blood from the stomach; while to take *oxymel scillæ* as an example of the diuretic action of acetic acid is peculiarly foolish. Mr. Abraham proceeds to say—"With regard to the process finally adopted by Mr. Dott for the estimation of nitrous ether, he will find that I suggested at Southport practically the same thing; but I omitted the acid as unnecessary, because the preparation contains something (not aldehyde, because that is not present in sufficient quantity) which so decomposes as to render the acid unnecessary. This something, which Mr. Dott entirely ignores, but which *I believe to be more probably* [the italics are mine] the chief ingredient wanted, is consequently so far estimated at the same time." I plead guilty to having ignored "this something," and I cannot comprehend how it is "estimated at the same time." Of one thing I am certain, that "this something" does *not* render the addition of acid unnecessary, unless perhaps the sample itself should be very acid. Possibly "this something" is only another name for *free acid*. I repudiate the idea that I was anticipated in any way by Mr. Abraham at Southport. In my paper, I did not refer to his method of employing iodide of potassium as a test (in which there is nothing new) because any reference could only have been condemnatory. Mr. Abraham then described (not for the first time) a process which is worthless; I have described a process which has at least some value.

David B. Dott.

Spirit of Nitrous Ether.

Sir,—Mr. Abraham, in his letter to the Journal of April 26th, is pleased to comment on two points of my paper on the above subject. On the first point, namely, "Diminution of the Separation Volume," he states that I found a greater loss in two winter months than he found in seven months, chiefly summer. Well, I have to remark on this statement that the loss which I record in specimen α was observed after twenty-two days, and in the case of β after seven days, not two months as stated by Mr. Abraham, who must have imagined this period. Moreover, the loss which Mr. Abraham records in his paper ('Year-Book of Pharmacy,' 1883, p. 553) was from "3-4" per cent. when fresh to 3 per cent. at three months, and 2 per cent. at seven months. Specimen β of my paper was carelessly stored for the purpose of showing how such conditions affect the quality of the spirit, so that I need not put Mr. Abraham's specimen in comparison with it. But specimen α was stored in the best attainable conditions of an ordinary pharmacy, and so kept, the separation volume decreased from 2 per cent. to 1·33 per cent. in twenty-two days; this specimen may fairly be compared with Mr. Abraham's, and by this comparison we find that the difference between 2 and 1·33 is less than that between "3-4" and 2, not greater, as stated by Mr. Abraham. These are small matters, no doubt, but they show that Mr. Abraham is exceedingly careless in his statements of fact.

He is very decided about the second point on which he remarks. He says that he believes my method for determining acidity "to be incapable of accurate results, as decinormal soda solution decomposes sweet spirit of nitre; indeed, any alkali does so more or less rapidly." This statement is a fair index of the manner in which he brings knowledge and wits to bear upon this subject. On this second point he entirely neglects to take into account the elementary chemical fact that during the titration the alkali unites with the free in preference to the combined acid (and this is the very basis of the method), so that decomposition of the nitrous ether, or of the aldehyde, is impossible in the circumstances.

While taking Mr. Abraham's remarks in good part, I cannot avoid expressing the thought that his utterance of inaccurate and misleading criticism is inexcusable and unjustifiable.

In a concluding sentence, I wish to remark that the statement that "any alkali decomposes sweet spirit of nitre more or less rapidly" should rather be written "more or less slowly." (I look upon the statement more as a generally accepted one rather than as an expression of Mr. Abraham.) Thus the U.S.P. allows twelve hours for the saponification of 10 c.c. with 1·5 gram of caustic potash; Dupré allows similar quantities to stand over night, and Muter allows an hour on a water-bath. These all indicate that saponification is slow. I wish, however, to add that it is not complete. Some time ago I allowed a quantity of spirit to remain in contact with large excess of strong soda solution for two days, and then subjected the mixture to distillation and found that all fractions of the distillate up to 100° C. gave the nitrous radicle reactions, and showing, therefore, that the saponification was incomplete. This experiment was undertaken for the purpose of obtaining indication of "paraldehyde," and the odour of the distillate was so similar to that of a spirituous solution of that body as to convey an impression of identity, but the temperature and the nitrous radicle reactions removed the impression.

Edinburgh. Peter MacEwan.

Standardized Tincture of Nux Vomica.

Sir,—Mr. Smith has correctly indicated an inexact point in the process I advocated for the titration of the mixed alkaloids in extract of nux vomica, but the margin of error involved is not great. Dragendorff, my authority, states that each c.c. of the test solution of the strength I recommend precipitates 0·00167 of strychnia, and 0·00197 of brucia. I have satisfied myself of the correctness of this statement as regards strychnia, but as I have no absolutely pure brucia in my possession, I have been obliged to assume that it is equally correct as regards the latter also.

The factor 0·00182 was found in the mean of the two figures above quoted. I was aware it would not yield absolutely correct results when the proportion of one alkaloid greatly exceeded that of the other, but the amount of error as illustrated by the differences shown in the twelve samples quoted in the table (page 443) would be within 0·5 per cent., and I scarcely considered this defect sufficient to outweigh the advantages that attend the process; nevertheless, it is well that attention should be drawn to the fact.

I feel much tempted to reply to Mr. Dunstan's letter in detail, but think on the whole it is better to postpone discussion upon our special points of non-agreement until he has completed and made known the further work on the subject I am so glad to hear he is engaged upon. In the meantime I quote with cordial approval the last sentence of his letter:—

"The production of standard galenical preparations of potent drugs, *which, in the majority of cases, needs the expenditure of a vast amount of preliminary scientific work*, marks out a distinct line of progress and research in the pharmacy of the future. I mean, I think so."

I have taken the liberty of italicizing some very important words in this sentence, and thus read it commends itself to my full approval.

G. F. Schacht.

Extract. Cinchon. Liq.

Sir,—I am delighted that Professor Redwood has taken the ext. cinch. liq. in hand, and heartily concur in his new process. *Apropos* of this matter, I may mention that for several times I have aided the exhaustion of the bark with acid. hydrochlor. dil., by which means an extract was obtained much more satisfactory than the ordinary method, so much so that I now offer the process for what it is worth. The bark is first exhausted with H_2O, only half the quantity the B.P. directs. Then the humid residue is macerated all night in H_2O with ℥j to 16 bark acid. hydrochlor. dil.; again exhausted, the first percolate evaporated to three ounces. No. 2 percolate is evaporated to a soft extract and this is then macerated in the first 3 ounces, then the whole made up to 4 ounces with s. v. r. A product is obtained doubly bitter to the ordinary and more deserving of the name. Suppressing all further comments, I will make bold to say (1st), that Dr. Paul's investigation proved how miserable a preparation the ordinary one is; (2nd), that in dil. acid. hydrochlor. we have an efficient solvent of the alkaloid left behind; (3rd), prolonged heat does not degrade the alkaloid in presence of acid mur., as the whole of the gas is easily dissipated at first; (4th) in a new edition of B.P. the old method ought to be expelled.

31, *Minto Street, Edinburgh.* D. Gorrie.

Hawking Chemists.

Sir,—I notice in your last number an account of a chemist whose man was fined for hawking laudanum. It appeared that the chemist was the proprietor of a van from which drugs, etc., were retailed round the country.

It is a fact that many chemists send out carts, which call at every roadside house, and sell everything, from tea to paregoric and paraffin. Is it any use for the Pharmaceutical Society to endeavour to raise our trade to a science when the public see educated men sending out drug-carts, only differing from the common hawker in that they emanate from a select dispensing establishment instead of a small huckster's shop?

Such practices prevent the public from looking favourably on efforts that are made to place us somewhat above the mixed grocer: and who can be surprised?

Chemist and Druggist.

Apprentice.—We do not consider the preparation to be hurtful if properly made.

F. Barry.—If you refer to the numbers of the *Pharmaceutical Journal* for the past year you will find some information upon the subject.

T. H. G.—We have not received any report of such a case. You will find information respecting the formula you inquire about in *Pharm. Journal* (1883), pp. 884 and 936.

Communications, Letters, etc., have been received from Messrs. Hemans, Francis, Moir and Son, Franklin, Associate, Datura, Marmor, J.D., F.S.G.

NOTE ON KAMALA.*

BY WILLIAM KIRKBY, PH.C.

Kamala was not known in Europe as a drug until a very recent period. Before the year 1852 the only account of it is in the writings of Anslie, Roxburgh, Royle, and Buchanan. In that year, however, Port-Surgeon Vaughan met with it in the bazaar of Aden under the Arabic name of *wars*. Specimens obtained by him were forwarded to Mr. Daniel Hanbury, together with information concerning the same. The following information collected by him is found in his 'Notes on Drugs observed at Aden, Arabia':†—"*Wurrus* or *warus* is a red powder used chiefly as a dye. It is the produce of a plant resembling sesame. The plant rises to about 5 feet in height, bearing several separate bunches or clusters of small round seeds, which are covered with a description of flour; this, removed by gentle rubbing, constitutes the dye. Two kinds come into the market. The best comes from the interior, principally from the towns of O Badan and Gebla, and the districts of Yaffaee and Sjibul Rudfan. The second kind, brought by the Somalis of the opposite coast, comes from Hurrer. The second quality is not so much valued, and does not realize the price of the kind which comes from the interior. A considerable quantity of the dye is exported to Bombay, being used at Surat by ladies for dyeing silk a light brown-yellow. The Arabs use it as a dye and as a medicine, internally, for leprosy, and externally, in solution, for freckles and pustules. Much of it finds its way to the Persian Gulf, being known as *asberg*." Dr. Vaughan goes on to say that the best quality sells for 24 rupees the maund, while the African variety sells for only 17 or 18 rupees the maund.

Mr. Hanbury‡ states that he showed the specimens he had received to Mr. Alexander Gibson, of Bombay, who was at that time in London. Mr. Gibson suggested to him that it was obtained from *Rottlera tinctoria*. He then proceeded to compare the drug with specimens in the museum of the Linnæan Society, and found that Mr. Gibson was correct in his surmise.

Kamala, as found in commerce, is a fine, mobile powder, of a dull red colour. Under the microscope it is seen to consist chiefly of translucent, bright red granules mixed with colourless stellate hairs. These hairs give the drug its dull appearance. The glands, Fig. 1, *a*, are spherical, rather

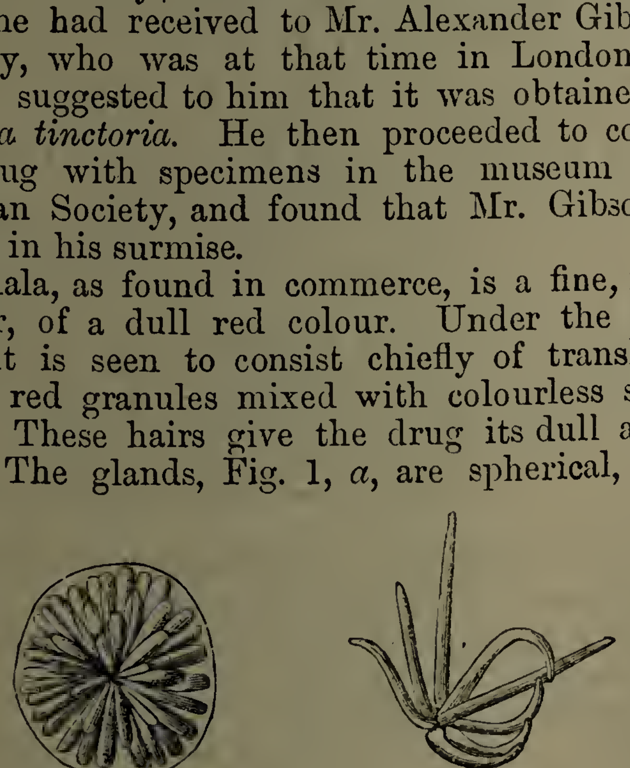

Fig. 1.
a. Gland of genuine kamala.
b. Stellate hair of the same.

irregularly so. Their diameter is from 70 to 120 mkm. (micromillimetres). They are flattened on one side, and are composed of a number of clavate cells enclosed in a pale yellow membrane. The cells are arranged in a radiate manner round a short stalk cell, which is not always visible, occupying the basal side of the gland. From ten to thirty of these cells may be seen on one side; the whole cell, however, contains from twenty to sixty of them. The cells are filled with a red resin, which is soluble in solution of caustic potash, alcohol, and ether. On treatment with solution of caustic potash the structure of the gland becomes plainly visible. On appropriate treatment, first with alcohol and afterwards with Schultz's solution or sulphuric acid and iodine, the cells are seen to be composed of cellulose, while the enclosing membrane is seen not to be cellulose.

Professor Flückiger* says that he examined authentic specimens from the Calcutta Gardens. These were taken from *Mallotus Phillipinensis* (*Rottlera tinctoria*), and he found them to agree entirely with the kamala of commerce.

From this it is plainly evident that the source of commercial kamala has been definitely settled.

Some years ago Messrs. Allen and Hanbury imported a remarkable kind of this drug from Aden. A full account will be found in 'Pharmacographia.' Mr. Hanbury forwarded a sample of this to Professor Flückiger, who submitted it to an exhaustive examination.† It differs from the ordinary variety in bulk, in having a *dark* red or violet colour. Microscopically examined it is at once seen to have quite a distinct structure. Solution of caustic potash dissolves the resin contained by the glands and the general structure is easily seen. The glands are cylindrical, somewhat conical, and are composed, like the other, of resin cells enclosed by a membrane. The arrangement of the cells will be best understood by reference to Fig. 2. The glands are

Fig. 2.
a. Glands of purple kamala.
b. Simple hair of same.

from 170 to 200 mkm. long and from 70 to 100 mkm. broad. The hairs mixed with them are simple and long, when compared with the short stellate hairs of the common kind. Professor Flückiger is quite sure the two kinds are not obtained from the same plant.

Dr. Dymock, in his 'Vegetable Materia Medica of Western India, says:—"'*Wurs*,' or '*wurrus*,' which differs from genuine kamala in being a dark purple colour, is the gland of the leaf of a leguminous plant, *Flemingia congesta*." He was not able to ascertain if it is collected in India or whether it is imported from Arabia. I have not had the pleasure of seeing Dr. Dymock's book; but it was the note, as above, which appeared in "The Month" of a recent number of the *Pharmaceutical Journal*, which first attracted my attention to kamala and its sources. Thinking it would be interesting to know if com-

* Read before the Manchester Pharmaceutical Association.
† *Pharm. Journ.*, [1], xii., 385.

* *Pharm. Journ.*, [2], ix., 279.
† *Pharm. Journ.*, [2], vol. ix., 279.

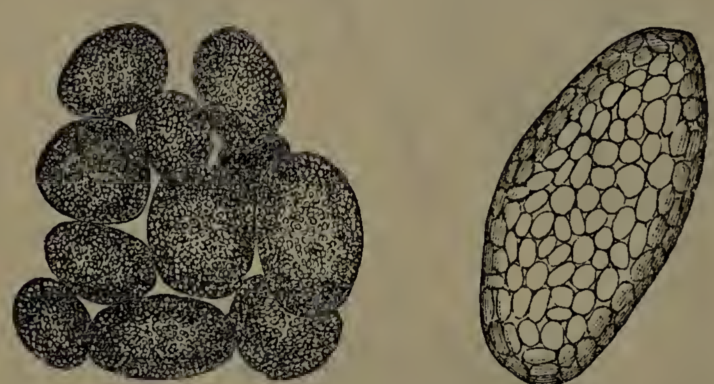
mercial kamala was entirely the produce of *M. Phillipinensis*, I obtained samples of the drug from various parts of the country. I find that everyone of the specimens obtained from dealers is genuine kamala.

Mr. E. M. Holmes, of the Pharmaceutical Society, has been kind enough to let me have samples of the specimens in the Society's Museum. The results of my examination are as follows:—

Sample marked "490 b," catalogued "Glands, covering fruit of *Rottlera tinctoria*," is genuine kamala.

Sample marked "490 c," catalogued "Wurrus, first quality," is identical with the purple variety examined by Professor Flückiger and is presumably the one referred by Dr. Dymock to *Flemingia congesta*.

Sample marked "490 d," catalogued "Wurrus, second quality."—This is totally different from either of the other two varieties spoken of. I have been unable to find any record of a third kind of this drug. I therefore venture to put before you a short description of this specimen. The glands are from 50 to 170 mkm. long, and from 50 to 100 mkm. broad. When seen with the microscope in a dry state they are translucent and but faintly coloured yellow. In form they vary very considerably; in fact, there appears to be no prevailing form. They impart but little colour to ether, alcohol, or solution of caustic potash. The cells are devoid of any such resin as is seen in the other two kinds. In solution of caustic potash they swell considerably, and their structure is rendered clearly visible. They consist of a mass of cells, composed of cellulose, enclosed by a non-cellulose membrane. The cells are not arranged in any particular manner. The general arrangement is shown, when seen in solution of potash, in Fig. 3, *b*. The hairs are similar to those found in the purple variety, being quite simple.



a *b*

Fig. 3.

a. New (?) variety of kamala seen dry.
b. The same seen in solution of caustic potash.

On drawing Mr. Holmes's attention to this unknown (?) variety, he informed me that he believed it was the *second* kind mentioned by Dr. Vaughan in his 'Notes,' and this sample was probably given by him to Mr. Hanbury, who presented it to the Museum.

I trust that some further information regarding the plants yielding the second and third varieties of "wurrus" will soon be forthcoming.

Looking at the last sort from an economic point of view, it would appear to be worthless as a dye, whatever it may be as a medicine.

In conclusion, I beg to tender my thanks to Mr. Holmes, and to Mr. Elborne who has assisted me in obtaining specimens of the drug.

THE MATERIA MEDICA OF THE NEW PHARMACOPÉE FRANÇAISE.

(*Continued from page* 839.)

N.

The articles omitted are Narcisse des prés, Nard celtique, Nicotiane rustique, Nigelle des champs. Those marked with an asterisk are Neroli ou Essence de Neroli and Nicotiane ou Tabac. The only alteration consists in the reference of the Bitter orange to the "Rutaceæ-Aurantiaceæ."

O.

The following are no longer official:—Orobe (*Orobus vernus*, L.), Orpin ou Reprise (*Sedum Telephinum*, L.), Ortie brulante (*Urtica urens*, L.), and Ortie dioique. Those marked with an asterisk are Orge (*Hordeum vulgare*, L.), Origan vulgaire and Ortie blanche ou Lamier (*Lamium album*, L.). The only addition is Orme fauve (*Ulmus fulva*, L.), the bark of which is better known in this country as slippery elm bark.

Opium.—This is said to be derived from *Papaver somniferum*, L., var. *album*, and to be the produce of Anatolia. This is scarcely correct, as the purple-flowered variety *β glabrum* is largely used in Asia Minor for the production of opium. Opium for pharmaceutical use should now yield when dried at 100° C. 10 to 12 per cent. of morphia and should afford about 50 per cent. of extract.

P.

Under this heading are omitted Pareira brava, Pavot noir, Pavot œillette, Pignon doux (seeds of *Pinus Pinea*, L.), Piment de la Jamaïque, Pin de la Caroline (*Pinus palustris*, Lamb.), Pin maritime, Poirée ou Bette, Poivre long, Polygala amer, Pomme de terre ou Parmentière, Pommier cultivé, Pouliot des montagnes (*Teucrium*, sp.), Pourpier cultivé (*Portulaca sativa*), Prêle d'eau (*Equisetum fluviatile*, L.) and Prêle d'hiver (*E. hiemale*, L.) Primevère (*Primula veris*, L.), and Pyrole ombellée.

The articles marked with an asterisk are Pariétaire (*Parietaria officinalis*, L.) Patience, Pensée sauvage (*Viola tricolor arvensis*, DC.), Pervenche grande et petite (*Vinca major* and *V. minor*, L.), Petit houx ou Fragon épineux, Pin sauvage, Poix de Bourgogne, Poix resine, Polygala de Virginie, Polypode commune. *Podophyllum peltatum* is the only addition under "P." It is placed in the *Berberidaceæ-Podophylleæ*.

Panama (Bois de).—This name now appears to be applied to *Quillaia*, as it is referred, with a note of interrogation, to *Quillaia Saponaria*, while *Quillaia savonneux* is omitted under "Q."

Patience (Racine de).—*R. obtusifolius*, L., and other species are now given as sources of this root, which in the last edition was described as Patience sauvage.

Pêcher.—The botanical name of the peach is now given as *Prunus Persica*, Mill., and the tree is referred to *Rosaceæ-Pruneæ*.

Persil.—The botanical name of parsley is now given as *Apium* (*Petroselinum*) *sativum*, Hoffm., and the leaves are no longer official.

Petit houx ou fragon épineux.—The natural order is now given as *Liliaceæ-Asparagineæ* and the official part is described as "souche" instead of rhizome.

Pin sauvage.—The young shoots commonly but wrongly, designated *Bourgeon de Sapin* are now official.

Poix de Bourgogne.—*Pinus Abies* is the botanical name now adopted.

Q.

Quintefeuille (*Potentilla reptans*, L.), is the only article omitted.

Quinquina Calisaya and Quinquina gris de Loxa only are marked with an asterisk.

Quinquina Calisaya.—Both the flat and quilled barks are official. Under the latter head the Java barks, known as *Ledgeriana* and *Javanica*, are apparently included. It is, however, almost useless to direct the flat bark to be employed, since the genuine flat *Calisaya* bark can scarcely be met with in retail trade. Barks which yield less than 25 per 1000 of crystallized sulphate of quinine are to be rejected. Barks which are rich in quinine, but which give bad officinal preparations, such as *Quinquina Pitayo* and *Q. lancifolia*, are to be reserved for the extraction of quinine.

Quinquina gris Huanuco.—This bark may now be obtained from *Cinchona micrantha*, R. P., *nitida*, R. P. and *peruviana*, How.

Quinquina gris de Loxa may be the produce either of *Cinchona officinalis*, L., or of *C. crispa*, Tafalla, and should contain at least 15 per 1000 of salifiable alkaloids, of which one-tenth should be quinine. The Indies, especially those belonging to England, are indicated as yielding these barks rich in alkaloids.

Quinquina rouge.—Both the flat and quilled barks are official, preference being given to the Dutch and English Indian quilled barks. Red bark should yield at least 30 per 1000 of the sulphates of the alkaloids of which at least 20 should be sulphate of quinine.

R.

Rhus radicans and *R. Toxicodendron*, Roquette cultivée (*Eruca sativa*, Lamk.), Roquette sauvage (*Brassica Erucastrum*, L,), Rose trémière (*Althœa rosea*, Cav.), and Rosier sauvage (*Rosa canina*) are omitted.

Raisin secs, Ratanhia, Réglisse, Rhubarbe de Chine, Riz, Romarin, Ronce sauvage (*Rubus fruticosus*), Rose à cent feuilles, Rose rouge (*Rosa gallica*, L.) and Rue are marked with an asterisk.

Ratanhia.—Under this name the root of two species is official, viz., Peruvian, and Savanilla or New Granada Rhatany. The latter is referred to Krameria (*Ixina Granatensis*, Pl. and Tr.), but the description given, "un brun pourpre sombre ou violacé," would seem intended to include the Pará rhatany (*Krameria argentea*, Mart.).

Réglisse.—The rhizome, as well as the root, is now official.

Rhapontic.—Rhubarb under this name, derived from *Rheum Rhaponticum*, L., and other species, is to be used exclusively in veterinary medicine.

Rhubarbe de Chine is described as the "tige et souche" of *Rheum officinale*, H. Bn. and of some other species, more particularly *Rheum palmatum*, Maxm., *Tanguticum*, L. The description given does not apply to the root of *R. officinale*, Bn., as cultivated and prepared in this country, but to the greater portion of the root imported from China.

Rose rouge ou Rose de Provins.—The buds are now directed to be deprived of the calyx.

S.

The articles omitted are Sagapénum, Sanicle, Saponaire d'Orient (*Gypsophila Rokejeka*, Del.), Sauge sclarée ou Orvale, Saxifrage grande ou Boucage (*Pimpinella magna*, L.), Schœnanthe de l'Inde, Schœnanthe officinal, Séséli de Marseille (*Seseli tortuosum*, L.), Soude commune (*Salsola Soda*, L.), Succin ou Karabé, Sumac des Corroyeurs (*Rhus coriaria*, L.), Surelle ou alleluia (*Oxalis Acetosella*, L.)

Those marked with an asterisk are Sabine, Safran, Sagou, L., Salsepareille du Mexique, Sang-dragon, Sangsue medicinale, Saponaire officinale, Sassafras, Sauge officinale, Scabieuse (*S. succisa*, L.), Scammonée d'Alep, Scille, Scolopendre, Scordium ou Germandé d'eau, Seigle ergoté, Semen contra, Séné, Squine (*Smilax China*, L.), Staphisaigre, Stramoine ou pomme épineux, Styrax liquide, Sucre de Canne and Sureau (*Sambucus nigra*).

Sucre de lait is the only new article.

Safran.—This is now attributed to *Crocus sativus*, L.

Salsepareille.—This is now said to be derived from a number of species of *Smilax*, the kind principally employed in France being La Salsepareille du Mexique, *S. Tuspan*, falsely called for a long time Honduras Sarsaparilla. It is said to be derived from *Smilax Medica*, Scht. et Cham.

Sandaraque.—This is now referred to *Callitris quadrivalvis*, Vent.

Santal rouge.—This is now referred to *Pterocarpus indicus*, W., with a note of interrogation, and to *Epicharis Loureiri* and *E. Bailloni*, Pierre. The remark in the last edition about a red resin, called dragon's blood, being obtained from *Pterocarpus indicus*, but which comes rarely into European commerce, is now omitted.

Saponaire officinale.—The stem as well as the root and leaf are now official.

Sassafras.—The wood instead of the root is now official.

Scrofulaire.—The root and flowering tops of *S. aquatica*, L., are now official, as well as those of *S. nodosa*, L.

Semen-contra, Semencine or Barbotine. — Under this name the young capitula of different species of *Artemisia*, *A. Cina*, Berg., *A. maritima*, *Stecheana*, Bess. (Stechmanniana ?), etc., are official.

Séné.—*Cassia lenitiva*, Bisch., is adopted as the botanical source of Alexandrian senna, and *C. angustifolia*, Vahl., for Tinnevelly senna.

Serpentarie de Virginie.—*Aristolochia Serpentaria*, Guib., is still adopted as the official species, although the rhizome usually met with in commerce is that of *A. reticulata*, Nutt.

Simarouba.—*S. amara*, Aublet, is now given as the source of Simaruba bark.

T.

The articles omitted are Térébinthe du pin d'Amerique (*Pinus palustris*, Lamb), and Térébinthe du Sapin balsamifere (*Abies balsamea*).

Tacamahaca.—This is now said to be the produce of *Icica heptaphylla*, Aubl. This resin should be completely soluble in alcohol.

Tanaisie.—The name now adopted for the tansy is *Pyrethrum Tanacetum*, DC.

Térébinthe d'Alsace.—The tree yielding Strasbourg turpentine is now given as *Pinus Picea*, L.

Térébinthe de Bordeaux ou Térébinthe commune is referred to *Pinus Pinaster*, Sol.

Térébinthe de Venise is now said to be obtained from *Pinus Larix*, L., instead of *Abies pectinata*, DC., as in the last edition.

Térébinthe de Chio is described as being greenish-grey, cloudy, with a feeble odour of turpentine and fennel; a sweet taste, aromatic, incompletely soluble in alcohol, but completely so in ether.

Tilleul.—The flowers are now referred to *T. sylvestris*, L., and *T. platyphylla*, Vent., which, however, are not here given as synonyms of *T. Europæa*, L.

U.

Uva Ursi, Raisin d'Ours is now placed here instead of under Busserole, and is referred to *Arctostaphylos Uva-Ursi*, L.

V.

The articles omitted are Valériane celtique, Valériane phu, Vermiculaire brulante (*Sedum acre*, L.), Verge d'or (*Solidago Virga-aurea*, L.), Véronique (*V. officinalis*, L.), Vétiver, Vipère, Vipérine commune.

Valériane officinale and Vanille are marked with an asterisk.

Valériane officinale is the name now adopted for valériane sauvage.

Vanille is referred to *Vanilla planifolia*, Andr. Vaniller (*V. Pompona*), which is an article of commerce in France, is therefore not admissible for use in pharmacy.

W.

The bark of *Drimys Winteri*, var. *granatensis*, is now official instead of that of the typical form. It is described as occurring in curved or quilled pieces 5–8 millimetres thick, whitish and marked with brown spots on its outer surface, the transverse fracture of a brown red colour, with large white striæ, which are transverse in the outer, and radial in the inner layers. Taste aromatic, very bitter and very pungent.

In comparison with the United States and British Pharmacopœia, one cannot but be struck with the large number of simples still retained in the materia medica, many of which are relegated in this country to the domain of the herbalist.

The botanical nomenclature and descriptions bear evidence of hasty work, which is further supported by the number of typographical errors which still exist in this part of the Codex.

TO PREPARE CORROSIVE SUBLIMATE GAUZE.*

In the New York Hospital, corrosive sublimate is used almost exclusively as an antiseptic upon gauze or jute. The sublimated gauze is prepared by immersing the bleached material in a solution as follows: corrosive sublimate, 20 parts; water, 4·480 parts; glycerine, 500 parts, for twelve hours; then wringing out, and allowing to dry, as far as the glycerine will permit. At the time of operation, a sublimate solution (1 in 1000) is allowed to trickle slowly but nearly continuously over the incision. Bleeding vessels are tied with sublimated catgut. No impervious protective is used over the dressings, as, by retaining the moisture of the dressings and the sweat, it is thought to act too much as a poultice. Metallic instruments must be immersed in a 5 per cent. carbolic solution, as the bichloride will form an amalgam with them. In New York Hospital, not only is the part to be operated upon washed with soap and water, but also with turpentine and alcohol, two ounces to the pint.

* From the *British Medical Journal*, April 5.

VALUATION OF GELATIN.*

BY F. PROLLIUS.

The author has determined the amount of ash, water and insoluble matter (residue insoluble in hot water) in various kinds of gelatin. To ascertain the gelatinizing property 1 part of the sample was dissolved in 90 parts of water, filtered, and the degree of viscosity determined.

	Ash.	Water.	Insoluble.	Time required for the solution to run out.
	p.c.	p.c.	p.c.	seconds.
Astracan from Schmidt and Dihlmann, Stuttgart	0·20	16·0	2·8	507
Ditto, from a collection.	0·37	18 0	0·7	485
Ditto. fine iridescent Russian quality, Tubingen collection	1·20	17·0	1·0	500
Ditto, Russian, from Gehe of Dresden	0·80	19·0	3·0	491
Ditto, in laminæ, from Gehe	0·50	19·0	0·4	480
Ditto, in threads, known as Hamburg threads	0·40	17·0	1 3	477

Indian isinglass	0·78	18·0	8·6	437
Yellow, quality unknown	2·30	17·0	15·6	360

To judge of the purity of isinglass, it is also recommended to subject the sample to microscopic examination.

MANGANESE VARNISH.†

The manganese varnishes are prepared by the use of manganous oxide, manganic oxide, manganese peroxide, and specially manganese borate. The last named compound gives a varnish of such excellent properties that it must be preferred to all other substances used for the same purpose.

Manganese borate varnish is prepared in the following manner: 2 kilos perfectly dry, white manganese borate, free from iron, in very fine powder, are gradually stirred into 10 kilos linseed oil, which is heated in a suitable vessel. By continual stirring a uniform distribution of the salt in the oil is effected. The heating is continued until the temperature of the oil reaches 200° C. It is to be observed, that a good quickly drying varnish can only be obtained when the manganese borate is entirely free from iron.

1000 kilos of linseed oil are then heated in the varnish kettle, until it begins to bubble. Then the mixture of linseed oil and manganese borate is run in, in a thin stream, the fire is increased, and the mixture is heated to a violent ebullition. After about twenty minutes boiling, the varnish is ladled out, filtered, while still hot, through cotton, and is then ready for use. Slabs of wood, which were immersed into the hot varnish, were coated with a perfectly dry, glassy layer, in from sixteen to eighteen hours.

It was shown by experiment, that manganese borate has the property of converting linseed oil, at comparatively low temperatures, into rapidly drying varnishes; a temperature of 40° is sufficient. If a small linen bag, containing 30 grams of manganese borate is suspended in a 10 litre flask, filled with linseed oil, the latter when placed in a warm place, will be converted into a good drying varnish in ten to fourteen days.

The Pharmaceutical Journal.

SATURDAY, MAY 10, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL REPORT.

IN accordance with the precedents of previous years the Council of the Pharmaceutical Society, at its meeting on Wednesday last, agreed upon the Report that should be presented to the members at the Annual Meeting on the 21st inst., and probably copies of it will reach the hands of many of our readers almost simultaneously with the present number of the Journal. We think it will not be taking a merely optimist view of the Report to say that, although some statements which might have been hoped for a few months ago will be found wanting, yet in respect to the regular business and progress of the Society the record which the Council is able to present of the past year's transactions is very satisfactory. It is undoubtedly disappointing that no apparent progress has been made towards securing ameliorative legislation, and that the Government has even declined to undertake the responsibility of introducing any Bill tramelled by provisions not directly relating to the sale of poisons. But such is the congestion of parliamentary business in the present session that the Government, with all its influence and notwithstanding repeated promises evoked by inquisitorial goadings, has not yet been able to introduce the Poisons Bill it is supposed to have prepared, and until this has been done it would be idle for the Council to approach Parliament with an independent measure. In the meantime the Council has not been unsuccessful in enforcing the present defective law. As many as one hundred and twenty cases of infringement have been dealt with, and in the majority of these the primary object—the compelling of the discontinuance of the illegal practices—has been attained without instituting legal proceedings, whilst in every case in which these have become necessary during the year the suit has been successful, and a penalty has been imposed. It may be remarked that this number probably by no means represents the whole of the complaints that have been received and investigated; but, judging by numerous communications that reach us, a large proportion of them would be concerning practices which, however objectionable, are not at present illegal, whilst others would contain complaints unsupported by evidence of the nature which is indispensable to success in proceedings in a court of law. Of minor importance, but not without its value to chemists and druggists in common with traders generally, was the service rendered by the Council in securing the modification of a clause in the Patents and Trade Marks Bill concerning the use of the royal arms, which might have been a source of vexation and trouble had it passed unaltered. A Medical Bill, also, has occupied the attention of the Council, not like its predecessors for what it contained, so much as for what it was deficient in, namely, a provision for the legal representation of pharmacists on any future Pharmacopœia Committee. The Council having failed by its representations to obtain this concession from the Department in charge of the Bill, is prepared to do its best to bring the unanimous wish of pharmacists in the most effective manner before the House of Commons should the Bill reach the stage of Committee.

In every other respect the Report shows that during the past twelve months the Pharmaceutical Society has enjoyed a fair measure of prosperity. The Financial Statement shows that the receipts from subscriptions have slightly exceeded those in the previous year, and that the income from all sources leaves a respectable balance over the expenditure. With many of the details in the Report relating to the Examinations, the Library and Museum, and the Benevolent Fund, our readers will already be more or less familiar, and they need not be further referred to here; but the opportunity may be taken to emphasize the compliment paid to those Local Secretaries who by their personal effort and perseverance contributed so much towards maintaining the stream of benevolence at the high level of the previous year.

Our pages this week also contain the Report of the local executive of the North British Branch, presented at the Annual Meeting of the members of the Pharmaceutical Society resident in Scotland, held last week in Edinburgh. It is satisfactory to find that the operations of the Branch continue to be carried on with success in all departments. One topic that appears prominently in this Report is the recent decision of the Council to acquire premises in Edinburgh more suitable to the requirements of the Society and its pretensions in Scotland than those at present occupied. It is evident that this step is much approved by the members of the Society living beyond the Tweed, and it may be hoped that the anticipation that it may lead to an immediate augmentation of the membership of the Society in Scotland will be fulfilled. In the course of the discussion upon the Report comments were made upon what was assumed to be an increased difficulty which had been introduced into the Preliminary examination coincidently with the enlargement of the time allowed to the candidates, and it will be observed that the subject was brought under the consideration of the Council at its meeting on Wednesday last. We are inclined to think that an undue importance has been attributed to the portion of the examination to which objection has been raised. It only needs a glance at the questions on p. 871 to see that the English sentences which were set for translation into Latin at the last "Preliminary" were of so simple a nature that they should present not the slightest difficulty to a boy capable of giving a fair translation of the passages either from Virgil or Cæsar, since in the course of his studies he would necessarily have gone over the ground covered by these questions again and again. It is also worthy of note, as pointed out by Mr. GOSTLING, that Latin is not the subject in which the majority of failures in the Preliminary examination occur. At any rate no reproach can be cast upon the examiner who set the questions, since the Regulations distinctly specify the "translation of simple sentences from English into Latin." Still, it is well that such points should be discussed as they arise, with a view to the clearing up of doubts, and those who think that too great a stringency is exercised have the assurance of the President that if their objections are reduced to writing and forwarded to him he will take care that they receive due consideration.

A NEW READING OF THE PATENT MEDICINES ACT.

IT may be that others besides ourselves have been startled within the last day or two by reading a statement seriously put forward at some length in the editorial columns of our contemporary the *Medical Press and Circular*, to the effect that no single day passes in the experience of a chemist transacting an ordinary retail business without his being guilty of transactions for which he exposes himself to fines amounting in the aggregate to, possibly, thousands of pounds. If this were true it would indeed be a serious discovery; but it cannot be said that the adjective "serious" is quite the one most applicable or it. In fact the article is a fresh illustration of the truth that "a little learning is a dangerous thing." Moved by the "persecution" which our contemporary considers to have been involved in a recent enforcement of a law to the somewhat arbitrary application of which retail chemists and druggists have had to submit for many years past, the *Medical Press and Circular* took up the study of the Act under which stamp duties are levied upon "patent medicines," and arrived at the startling conclusion that stamp duty is chargeable upon all "preparations whatsoever to be used or "applied externally or internally as medicines or "medicaments, for the prevention, cure, or relief "of any disorder or complaint incident to or in "any wise affecting the human body, made, pre-"pared, uttered, vended, or exposed to sale by any "person or persons whatsoever." Being under this impression our contemporary sees an imaginary danger threatening chemists in that "any one of "the class may, to-morrow, be summoned for "selling to an informer a pennyworth of sper-"maceti ointment," and fears that even a medical practitioner dispensing his own prescriptions is liable to be brought under the penal clauses of the Act, unless he retains a supply of stamps "ready for affixing to each bottle or box that leaves his surgery." Indeed, our contemporary appears to have completely misread the remainder of the paragraph quoted, according to which the essence of the liability to stamp duty consists in the medicine or preparation being put forward as a secret, patent or proprietary article, or being advertised in any way as being beneficial in the prevention, cure or relief of any ailment affecting the human body. This may be easily illustrated by the case which has excited so much of our contemporary's sympathy. Unless we are greatly in error, a mixture of menthol and wax might have been sold as such, to any extent, without the seller being liable to pay one penny of stamp duty; but as soon as the mixture had once been advertised to the public, in newspaper, hand-bill, label, or any other medium, as capable of relieving headache, the conditions were changed, and the stamp duty became chargeable on every separate quantity sold. We have referred to this subject at somewhat greater length, perhaps, than it deserved, because the article in our contemporary is capable of disturbing effectually the equanimity of any nervous chemist and druggist who may read it, and not have a sufficient cognizance of the Act, 52 Geo. III. c. 150, to enable him to perceive the error. Otherwise the mistake would be almost too grotesque for serious discussion, for we are quite able to agree with one opinion expressed by our contemporary, that "the ludicrous side of the subject is as prominent as the grave aspect of it."

The Annual Dinner of the North British Branch took place in the Royal Hotel, Edinburgh, on Tuesday evening, April 29, Mr. Nesbit, President, being in the chair and Mr. Gilmour, Croupier. In responding for "The Pharmaceutical Society of Great Britain," Messrs. Borland and Young made very stirring speeches in reference to the position of the Society in Scotland and the acquirement of new premises. Mr. Borland, in strongly urging members to use their personal influence to get others to join the Society, gave a sketch of the present membership and showed in what directions it might be increased. The gathering was numerously attended and was an exceedingly harmonious and successful one.

* * *

It appears from a circular sent out by the secretary of a provincial association that a statement has been made by the local inspector of weights and measures to the effect that an Order of the Board of Trade has been received by him requiring that all chemists' measures shall have their denominations marked on them, and that symbols alone shall not be allowed. We are in a position to state that no such "Order" has been issued, the fact being that the

Board of Trade has no power under the Weights and Measures Act to take such a step. We understand, however, that it is the opinion of the Standards Department that apothecaries' measures should have their denominations marked on them "in legible figures and letters," as this appears to be required by the Act of 1878, and this opinion was indicated in the "Suggestions" as to the testing of apothecaries' graduated glass measures and apothecaries' weights which were issued to inspectors in May, 1881.

* * *

In reply to a question put by Mr. Warton in the House of Commons on Thursday, as to when the Government intended to introduce into the House of Lords the promised Bill on patent medicines, Mr. Mundella said that the Sale of Poisons Bill, which would deal with this subject, would be ready in a few days.

* * *

In accordance with an intention intimated at a recent Evening Meeting, Mr. Giles has given notice of a motion which he will propose at the Annual General Meeting of the Pharmaceutical Society, to the effect that the Council be requested to consider the best means of promoting systematic research, having for its primary object the initiation, examination and improvement of formulæ for the national pharmacopœia.

* * *

We think it may be useful to repeat here that tickets for the Annual Dinner should be obtained from the Honorary Secretary, Mr. Richard Bremridge, on or before Saturday, the 17th inst.

* * *

At a recent meeting of the Paris Pharmaceutical Society a commission was nominated, consisting of Messrs. Petit, Ferrand, Portes, Thibault and Champigny, and entrusted with the duty of bringing under the notice of the Minister "the numerous errors and omissions of the new Codex." The Commission has issued an appeal to all *pharmaciens* for assistance and requesting that suggestions may be made to the President, M. Petit.

* * *

The next meeting of the Chemical Society will be held on Thursday, the 15th inst., when the papers read will be:—"On the Indices of Refraction of Organic Substances," by Dr. J. H. Gladstone; "On Fluorene Derivatives," by Mr. W. R. E. Hodgkinson; and "Some Minor Researches on the Action of Ferrous Sulphate on Plant Life," by Mr. A. B. Griffiths.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, May 15, at 8 p.m., when papers will be read on the "Botany and Materia Medica of Linseed," by Mr. E. H. Earle; on the "Chemistry of Linseed," by Mr. E. Cullinan; and on the "Separation of Cobalt and Nickel," by the Reporter on Analytical Chemistry, Mr. C. Thompson.

* * *

The Annual General Meeting of the Chemists' Assistants' Association will be held at 53, Conduit Street, on Wednesday, May 14, at 9 p.m. precisely, when the report for the past session will be read and the Council for the ensuing year will be elected.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 7, 1884.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Robbins, Savage, Schacht, Symes, Williams, and Young.

The minutes of the previous meeting were read and confirmed.

THE LATE MR. SQUIRE.

The PRESIDENT said he could not commence the business of the day without referring to the loss sustained by the Society and by all British pharmacists, in the death of one its Founders and past Presidents, Mr. Peter Squire. It would be scarcely possible to find anyone who could speak of him as one who had laboured so long should be spoken of, from personal experience. He, himself, had known Mr. Squire for something like twenty years, first as an examinee, afterwards as a colleague on the Board of Examiners and as a member of the Council, and those who, like himself, had had the honour of working with him during the later years of his life must have been struck by the wonderful activity and keenness of perception he always showed. It was a marvel to his younger colleagues to find so much energy and fire in a man whose life had been one of such unceasing activity. The fact that he had departed with the honour and glory of a ripe old age made the reference to his death less saddening than it otherwise would be. Not many could expect to reach the age of eighty-six and few could expect to do the vast amount of work which Mr. Squire achieved during even the last twenty years of his life. He might further say, knowing something of the opinions held of Mr. Squire in the outside world, social and otherwise, that no man could be more correctly described as a typical pharmacist; and the respect in which he was held outside the Society's house was an indication of the honour which he had, by his labours, conferred on pharmacy. He would move the following resolution:—

> "That the Council wishes to express to Mrs. Squire and her family its most sincere sympathy at the loss which they have sustained in the death of Mr. Peter Squire, one of the Founders and past Presidents of the Society, and to convey an assurance of the high esteem in which he was held by the Council for the valuable services which he rendered to pharmacy and to the Pharmaceutical Society."

The VICE-PRESIDENT, in seconding the motion, said he had not had the advantage of knowing Mr. Squire as intimately as those resident in London, but he had been acquainted with him for the last thirty years, and he ventured to think that no name in the country was better known, since his 'Companion to the Pharmacopœia' was on the shelves of almost every pharmacy.

The motion was carried unanimously.

DIPLOMAS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Ashton, Frederick William.
Cule, Taliesin.
Dobson, George Turner.
Granger, Harold.
Jones, Morgan Isaac.
Luxmoore, Charles Mann.
Marshall, Sam.
Milford, James Emery

Neve, Annie.
Spilsbury, James
Wood, John

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Ashton, Frederick William ...Chertsey.
Austin, Alfred ....Bournemouth.
Corder, Walter Shewell ....Kendal.
Cule, Taliesin ....Pontypridd.
Granger, Harold ....Hucknall Torkard.
Houfe, Robert William ....Bradford.
Jones, Morgan Isaac ....Trecynon.
Luxmoore, Charles Mann ......Bristol.
Marshall, Sam ....Hyde.
Milford, James Emery ....Manchester.
Neve, Annie ....Eastbourne.
Puckey, Courtenay ....Stanstead.
Selkirk, James ....Cork.
Spilsbury, James ....Leamington.
Wood, John ....Leighton Buzzard.

Chemist and Druggist.

Job Preston, of Sheffield, who was registered as having been in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society.

Aspinall, William ....Platt Bridge.
Atkinson, Charles Henry ......Heckmondwike.
Attwood, Henry Ernest ....London.
Bain, John...........................Liverpool.
Bates, Edward .. .. Brackley.
Bennison, Richard ....North Ormesby.
Bostock, Thomas Henry.........Eastwood.
Cardwell, Augustus...............Ossett.
Coates, Udolphus Aylmer ......Walsall.
Doubleday, Frederick William..Dorking.
Dow, William ....Kinross.
Gilkes, Frederick George ......Banbury.
Grant, Thomas......................Clevedon.
Green, William James............London.
Hands, Henry Joseph............Chipping Campden.
Harrison, Jeremiah...............Blackburn.
Hedley, Charles Alfred ....London.
Hendry, Robert Love ....Edinburgh.
Hodgkinson, Peter James ......Manchester.
Hudson, William...................Sunderland.
Illingworth, George Skeen ......Glasgow.
Jarvis, Clarence Frank ....Birmingham.
Jenner, Charles Samuel ....London.
Jones, George ....London.
Keith, John ....Newton Stewart.
Kemp, Herbert William.........Horncastle.
Kerr, William ....Dunfermline.
Lambert, John Thomas ....Wombwell.
Lees, James ....Watford.
MacNeilage, Alexander ....Greenock.
Masters, Henry James ....Bath.
Maxey, William Henry ....Sheffield.
Perkins, Thomas James ....Ealing.
Pitts, William Christopher......Norwich.
Price, Henry Thomas ....London.
Richards, Jonah Palmer ....Carmarthen.
Riddiough, Fred. ....Keighley.
Rigg, George Farrer ....Kendal.
Rogers, Oliver ....Tunbridge Wells.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

THE PRELIMINARY EXAMINATION.

Mr. BORLAND asked if a failure in the translation of English into Latin militated against the success of candidates at this examination.

The PRESIDENT replied that he did not think it did, or only partially. It was used by the examiner mainly to see that the candidates did not translate Latin into English by learning by heart an English edition of the author.

Mr. BORLAND said the question was broached at a meeting recently held in Edinburgh, and reference was made to what seemed to be an innovation, to a certain extent, viz., that the English sentences for translation contained words which were not to be found in the Latin sentences which were given for translation. At the time when he was connected with the Board of Examiners in Scotland, a discussion took place on this practice, and it was only agreed to on the understanding that the English words which had to be translated were to be found in the Latin sentences,—not the individual words, of course, but the root, so that the student would only have to put it into the right case, mood or tense, as the sentence required. It was considered that it would be a hardship on the candidates to have to spend a considerable amount of time searching for the Latin word best suited to express the meaning.

The PRESIDENT thought Mr. Borland was rather confusing parsing with translating.

Mr. BORLAND said he thought not.

The PRESIDENT said the examination paper contained first a piece of Latin to be translated into English, from Cæsar or Virgil; and then there were a few little sentences in English to be put back into Latin, besides the parsing.

Mr. BORLAND said he referred entirely to translating English into Latin; and it was considered at the time of the discussion he referred to, that in giving sentences of that kind, the words in the English sentence should be found in the Latin passage which was given for translation into English, in some form or other. In looking at the sentences given at the time he found such was the case, but this was not so on the last occasion.

The PRESIDENT thought the words given were to be found in the author, and in that part of the book which the candidate had to study.

Mr. BORLAND was not quite sure of that.

Mr. WILLIAMS suggested that this matter was one rather for the Board of Examiners than for the Council.

Mr. BORLAND said his main point was whether a failure in this matter would tell against the candidate, and he thought this ought to be known, because otherwise a candidate might spend a great deal of time on one subject and so hardly do himself justice in others.

Mr. HAMPSON thought Mr. Borland was quite right in calling attention to the subject, which was considered a grievance.

Mr. YOUNG said the same view had been put forward by Mr. Borland when the question was discussed by the Board of Examiners in Scotland. He did not himself see that it made much difference that the exact words were not found in the sentences given, if they were in the book.

Mr. SYMES remarked that as the subjects were divided into three parts, and the matter in question came at the end of the Latin portion, the candidate would not spend extra time over that until he had finished the other portion. But he could not see how a failure in this subject would not tell against him; if it were so, what was the use of introducing it? The candidate was supposed to have at his fingers' ends the power of translating any portion of the particular book selected. It would be well for Mr. Borland to ascertain the exact sentences which were given, and if they were not found in the book selected he should support him.

The PRESIDENT said the examination had for some years been in the hands of the College of Preceptors, which body had had large experience, and he thought the Council would not like to interfere with it in any way. He remembered being told by an examiner of the College that the translation of these sentences into Latin was a distinct gain to the candidates. The object of the examination was to ascertain that the candidate had such a knowledge of elementary Latin as should enable him to become a fair translator of prescriptions by-and-by. Some young men might make a very slovenly translation of a paragraph from Cæsar or Virgil, and yet might do very well with these little sentences. He hoped Mr. Borland would give the College of Preceptors credit for providing the candidate the best opportunity of showing his general knowledge of elementary Latin.

Mr. BORLAND said that was his own idea entirely. He thought it was one of the best tests a young man could be subjected to, to translate English into Latin, but it was in his opinion a hardship on the candidate to have to search for the words required.

The PRESIDENT thought it was in a great degree a matter of individual judgment.

The VICE-PRESIDENT differed from Mr. Borland entirely, and thought it highly desirable that the candidates should show a knowledge of Latin words.

Mr. ANDREWS thought the sentences set were exactly of the same character as those in Smith's 'Latin Course.'

Mr. CHURCHILL thought it was a great mistake to lead candidates to suppose that this translation into Latin would not count against the candidate. If a man pretended to know anything of any language he ought to be able to translate into and from it with equal facility.

Mr. SCHACHT said the Council ought to take the sole responsibility of these examinations on itself and not throw it on to the examiners. The regulations laid down plainly included the translating of English sentences into Latin, and did not prescribe that they should be taken from the same book as the other Latin examples. They might occasionally differ as to the selection of any particular sentence, but that must be left to the examiner's judgment.

Mr. GOSTLING remarked that as a rule Latin was not the subject in which candidates failed.

The PRESIDENT said there was a very large margin allowed, within which a candidate was permitted to pass, and the examiners, who were experienced men, were ready to make all fair allowances.

Mr. SAVAGE suggested that if the Board of Examiners in Scotland had any suggestions to make it should communicate with the Board of Examiners in England, so that, if possible, they might agree.

The PRESIDENT said it had been shown by Mr. Schacht that the examination was quite within the regulations laid down by the Council, but if Mr. Borland or any other member had any ideas or suggestions with regard to the examination and would let him have them in writing, he would take care they should be submitted to the College of Preceptors. He had, from time to time, received letters from members containing observations on the examinations, derived from the experience of their sons, which he had submitted in this way, and such communications the College of Preceptors was always glad to receive.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and various accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£15 to the widow (aged 53) of an annuitant and member from 1842 to 1870, and subscriber to the Fund. The husband died in January last; applicant is suffering from inward tumour, and is dependent on her children for support. Middlesex.

£15 to a former pharmaceutical member, 1841 to 1851, and subscriber to the Fund, aged 73. Applicant was in business for forty-six years, but in consequence of his ill-health, the business gradually dwindled away. Devonshire.

£5 to the widow of a registered chemist and druggist, aged 63. Applicant had a grant of £5 in July, 1879. Is now in ill-health and with no friends who can assist her. Yorkshire.

Two other cases had not been entertained by the Committee.

The Secretary had reported that members and subscribers in various parts of the country had written and sent him letters they had received asking for pecuniary assistance.

The Committee expressed a hope that all such cases should be referred to the Secretary, so that proper investigations might be made.

The VICE-PRESIDENT, in moving the adoption of the report, desired to draw special attention to the last paragraph.

The report and recommendations were unanimously adopted.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
March	Day	436	26	9	17
	Evening	181	20	3	8

	No. of Entries.		
Circulation of books.	Town.	Country.	Total.
March	176	134	310

Carriage paid, £1 14*s*. 6*d*.

The undermentioned donation to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the donor:—

Gay (F.), Essai d'une Monographie locale des Conjuguées, 1884.

The Committee recommended the purchase of the undermentioned works for the Library:—

Flückiger (F. A.), Cinchona Barks, pharmacognostically considered, translated by F. B. Power.

Moens (J. C. B.), Cinchona Cultivation in Asia from 1854 to 1882.

Mueller (F. von), Eucalyptographia, decades 1 to 5, and 7 to end.

The Committee approved of the purchase of the following:—

Berichte der deutschen chemischen Gesellschaft. Sundry numbers to complete vols.

Curator's Report.

The Curator had reported the attendances in the Museum during March to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	582	40	5	19
Evening	148	16	1	4

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors and a special letter to Dr. Domingo Parodi:—

A collection of the indigenous drugs of Brazil and neighbouring countries, containing two hundred and fifty-seven specimens.

From Dr. Don DOMINGO PARODI, forwarded by Mr. W. B. Cranwell.

Specimen of Oil of Limes from Trinidad.

From Messrs. WRIGHT, LAYMAN AND UMNEY.

Specimen of Citroptene obtained from the "Oil of Limes." From Mr. J. O. BRAITHWAITE.

STATEMENT OF ATTENDANCE OF MEMBERS OF COUNCIL ON COMMITTEES FOR THE YEAR 1883-84.

NUMBER OF ATTENDANCES OF MEMBERS OF COUNCIL AT COUNCIL MEETINGS FOR THE YEAR 1883-84.

Andrews, Frederick	8
Atkins, Samuel Ralph	11
Borland, John	9
Bottle, Alexander	10
Butt, Edward Northway	11
Carteighe, Michael	11
Churchill, Walter John	9
Gostling, Thomas Preston	7
Greenish, Thomas	11
Hampson, Robert	11
Hills, Walter	11
Radley, William Valentine	11
Richardson, John George Fredk.	10
Robbins, John	11
Savage, William Dawson	11
Schacht, George Frederick	11
Squire, Peter Wyatt	6
Symes, Charles	10
Williams, John	10
Woolley, George Stephen	8
Young, James Robertson	10

Number of Meetings during the year, 11.

Specimens of the α and β Amylsulphates of Barium and of Cerotate of Lead obtained by the oxidation of paraffin. From Mr. W. H. INCE.

Fine specimens of Crystallized Bismuth, Iodide of Lead and Sesquichloride of Chromium. From Mr. E. B. VIZER.

Specimens of Sodium Hydrate in crystals. From Mr. R. A. CRIPPS.

Specimen of Phosphoric Acid in fine crystals, and Potassio-ferric Oxalate in crystals. From Mr. P. L. HUSKISSON.

The Professors had attended and reported satisfactorily of their respective classes.

A draft of the Annual Report had been submitted and agreed to.

The Council went into committee to consider the draft Annual Report.

On resuming, it was adopted and ordered to be printed, and the report of the Committee was also adopted unanimously.

FREEHOLD INVESTMENTS.

The report of this Committee stated that one of the purchases sanctioned last month had gone off, the property having been sold while the purchase was under the consideration of the Council, and recommended that the Committee be entrusted with powers sufficient to conclude a bargain when the property had been approved by the surveyor.

The PRESIDENT having explained the subject, the report and recommendations of the Committee were adopted.

NEW PREMISES IN EDINBURGH.

The PRESIDENT reported that the bargain for the premises at 36, York Place, Edinburgh, had been concluded at a price of £1900; the completion of the sale to take place on the 15th inst. He laid on the table plans of the floors and of the elevation of the house, and stated the alterations which the Committee considered it desirable to make in the premises to fit them for the use of the Society.

The Council went into committee to consider the details of this matter.

On resuming it was resolved that the alterations and improvements recommended by the Committee be carried out under the supervision of the local members of the Committee.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor stating the progress of cases which had been placed in his hands.

Franklin Goforth, 33, Bridge Street, Runcorn, had paid the amount of penalty and costs into Court.

W. E. Taylor, 3, Victoria Buildings, Burgess Hill, had paid the amount of penalty and costs into Court.

Several cases of alleged infringement of the Act had been considered by the Committee, and recommendations were made in respect thereof.

The report was as usual considered in committee. On resuming, the report and recommendations of the Committee were adopted unanimously.

APPLICATION FOR REMISSION OF A PENALTY.

The following communication was read:—

"Treasury Chambers,
"5 *May*, 1884.

"The Registrar of the Pharmaceutical Society,

"Sir,— I am directed by the Lords Commissioners of Her Majesty's Treasury to forward to you two letters in original of the 23rd and 30th ulto. relative to a penalty mposed on Mr. E. A. Browne for an offence apparently against the Pharmacy Act; and I am to request you to submit them to the Council of the Pharmaceutical Society, and to inform my Lords, in order that they may answer Mr. Browne, whether, in the opinion of the Council there is any reason for remitting the penalty or any part of it.

"My Lords have before them the letter (17602) from the Treasury to the Registrar of your Society of 21st February, 1877,* and they have no intention by this present reference of withdrawing any part of it.

"I have the honour to be, Sir,
"Your obedient servant,
(Signed) "R. E. WELBY."

After having fully considered the circumstances of the case referred, it was resolved that a reply should be addressed to the Treasury, stating that in the opinion of the Council there is no reason for remitting the penalty or any part of it.

The PRESIDENT said that the person referred to in the Treasury letter had also sent an application to the same effect to the Council, to which he recommended that a similar answer be returned.

This was agreed to.

REPORT OF EXAMINATIONS.

April, 1884.

ENGLAND AND WALES.

RESIGNATION OF AN EXAMINER.

The PRESIDENT read a letter from Mr. H. B. Brady, resigning his position on the Board of Examiners, and moved—

"That this Council desires to place on record its high appreciation of the services rendered to the Society by Mr. H. B. Brady, F.R.S., during the twelve years he has been a member of the Board of Examiners for England and Wales."

The motion was seconded by the VICE-PRESIDENT and carried unanimously.

THE BOTANIC GARDENS.

A letter was read from the Secretary to the Royal Botanic Society stating that the usual facilities would be afforded for students visiting the Gardens of the Society in Regent's Park, on the conditions hitherto observed.

* *Pharmaceutical Journal*, [3], vol. vii., p. 737.

NORTH BRITISH BRANCH.

Annual Meeting.

The Annual Meeting of the North British Branch was held in the Society's Rooms, Edinburgh, on Tuesday, April 29, at 4 o'clock afternoon.

Mr. John Nesbit, President of the Branch, took the chair and called upon the Secretary to the Branch to read the

Annual Report.

The Council of the North British Branch of the Pharmaceutical Society of Great Britain have pleasure in submitting their Report for the past year.

The operations of the Branch continue to be carried on with success in all departments. Owing to the early expiry of the lease of the present premises, the question of increased accommodation has again recurred. The limited accommodation of the present rooms has long interfered with the work of the Society, the attendant inconvenience being particularly felt on examination days. It has therefore been determined by the Council of the Society to purchase a house better adapted to the existing requirements and capable of extension should the Branch extend in usefulness and influence. Your Council feel that the accommodation afforded by the house, No. 36, York Place, the purchase of which has been effected, will not only serve the required purposes, but that it will give the Society a position superior to that which it has hitherto held in Scotland. With the change which will occur before the next Annual Meeting, your Council look forward to increased zeal on the part of Scotch adherents of the Society, and augmentation from those who have not yet availed themselves of the advantages offered by it.

During the past year the Library and Museum have been greatly enriched by valuable donations. To the Library several valuable works of reference and scientific periodicals have been added by purchase, and the donations to the Museum have been more than sufficient to fill up the available space.

Many students from all parts of the country continue to take advantage of these departments. To visitors fully three hundred volumes have been lent out from the Library, and for reference it has even more largely than usual been used by those connected with the Society. The number of visitors to the Museum during the past year has been 1514, namely, 980 during the day and 534 in the evening. It is hoped that in the new premises the Library and Museum will always be available for study, as these departments at present are in London.

The Secretary to the Branch reports that a larger number than hitherto of tickets for courses of lectures in botany and chemistry have been issued to pharmaceutical students, and it is pleasing to note that one of them is the Silver Medallist in one of the courses of chemistry lectures, while the names of several others occur in the honours list. Provincial as well as local students now come forward to these classes, and it is noteworthy that there is a growing desire on the part of young pharmacists to undergo a course of instruction in practical chemistry. Many from all parts of the country now spend a short time here in such preparation under recognized teachers. Your Council feel that these circumstances are a strong indication that our young men appreciate the advantage of a systematic course of study, and if they voluntarily undergo a modified curriculum, it is hoped that a well arranged and compulsory one will act more as a stimulus than as a retardation to their progress.

During the winter five evening meetings have been held and a sixth was arranged for April, but owing to examinations and other causes it was not proceeded with. The papers which have been read have in all but two cases come from members of our own profession, and have been marked by their practical importance and general interest. Your Council desire to record their indebtedness to those who have communicated the results of their labours at these meetings. Interesting discourses on subjects allied to pharmacy have also been delivered by Dr. Macadam and Mr. Geddes, and to these gentlemen your Council desire to express their thanks.

In the course of the year the Board of Examiners for Scotland have had four meetings for examination, extending over twelve days. The total number of candidates examined was 146, a large increase over the preceding year. This increase was in Minor candidates, of whom 134 were examined, 59 being successful and 75 being rejected, showing failures to the extent of 56 per cent. nearly,—a rate which, your Council cannot but admit, is distressingly high. Eleven Major candidates were examined, of whom 5 were successful, and also one Modified candidate. For the Preliminary examination 245 candidates have presented themselves at the various centres in Scotland, and the results of the examinations show that 138 have passed. The failures thus number 43·6 per cent., a slight increase over the previous year, but yet under the percentage (49·96) for Great Britain.

Your Council look forward with interest to the effect of the recent change in this examination. Candidates are now allowed one and a half hour for each subject, the object of this extension of time being to allow justice to be done to each portion of the paper.

Your Council regret that the Pharmacy Acts Amendment Bill, which the Council of the Society submitted to the Lords of the Privy Council at his invitation, was not brought into Parliament last session, owing to the slow progress of business in the House of Commons. The prospects of the introduction of the Bill during this session have not brightened; indeed the Lords of the Privy Council has intimated to the President of the Society that it is the intention of the Government to introduce a Bill dealing with the whole question of the regulation of the sale of poisons, but that the Bill will not affect the constitution of the Pharmaceutical Society. Your Council feel that the position of pharmacists cannot fail to be affected by any legislation dealing with the regulation of their calling, and they look forward to the introduction of the Bill with a jealous regard for the interests of pharmacy

In connection with the revision of the British Pharmacopœia, your Council received a communication from the British Medical Council similar in terms to that addressed to the Council of the Society. The communication was referred to a small committee which has not felt it expedient to proceed in the matter pending the action of the Council of the Society to obtain statutory pharmaceutical representation on the Committee for the compilation or revision of the national Pharmacopœia.

In the Report of the Committee of Scrutineers on the voting for the fourteen vacancies occurring in the Council at this time, it will be observed that there is a satisfactory increase in the number of voting papers sent out to the members and associates in business in Scotland, namely, 272, as compared with 247 last year. This gives a fair indication of the steady progress which the Society has been making in Scotland during the past few years: thus, at the end of 1880, the number of adherents was somewhat over 300, while at the end of 1883, they had increased to 409, and it is gratifying to note that a goodly number have been elected this year. With the increased inducements now offered, your Council feel that greater prosperity is yet attainable, and they trust to the support of all Scotch adherents in advancing the interests and furthering the objects of the Society.

Mr. Maben (Hawick), in moving the adoption of the report, said that he considered it as satisfactory a one as had been submitted by the Council of the Branch. The leading feature was undoubtedly that which referred to the acquirement of new premises in Edinburgh. The step which the Council of the Society had taken in this matter was one of the utmost importance to the Branch, and would be advantageous to the Society at large. He had always felt that in Edinburgh, a city of academies and the most important centre of medical education, the Society should occupy a prominent position. Independent of mere position, it would not be forgotten that increased accommodation implied increased facilities for business and for study, and attraction as a house of call for country members. He hoped that the opening of the new premises would be marked by some distinctive feature, in the way of demonstration and increase of Scotch membership. He was glad to learn from the report that the Society was making progress in Scotland; the additions might be few, no doubt, but that was because the number engaged in pharmacy in Scotland formed a comparatively small proportion of those on the Register, and they had nothing to be ashamed of in the progress which was going on. The results of the examinations were a part of the report which would interest everyone, particularly that which referred to the Preliminary. A change was recently made in this examination which was understood to be in the interest of the candidates, namely, increasing the time given for answering the questions, and so dividing the work as to allow a specific subject for a given time. That, he felt, to be an admirable change. But when one looked at the papers which had been given since the innovation it would be seen that not only was the time increased, but that the amount of work also was increased in at least a corresponding proportion, and, further, that the nature of the work was increased in difficulty. This, he considered, most unsatisfactory, and the result was seen in an increase of failures over last year. He was expressing the feelings of many country pharmacists in saying that this was a matter which required looking into. In commenting on the Pharmacy Acts Amendment Bill, he expressed the hope that it would be enacted ere long, and that the responsibility of prosecutions in cases of infringement would be transferred from the Society to the public prosecutors.

Mr. Tocher (Helensburgh) seconded the motion.

Mr. Borland said that there was one point which Mr. Maben had adverted to in his remarks on the Preliminary examination, in which he was at one with him, and which he properly referred to as a greater degree of severity. Probably the increase was apparent in the examination as a whole, but he thought that it was chiefly evident in the passages for translation from English into Latin. These passages were, he thought, a complete departure from what was intended when they were introduced. It was intended that they should bring out the candidate's knowledge of grammatical construction, but as now given they demanded a verbological knowledge which should not be expected of them. He felt very strongly in this matter, and was glad that the subject had been referred to.

The discussion on this subject was continued by Messrs. Frazer, Gilmour, Kinninmont, McAdam, McLaren, Stephenson and Young, a general opinion in favour of Messrs. Borland and Maben's remarks being expressed.

Mr. Murdoch (Falkirk) wished to draw attention to a subject which was of some importance to those connected with the Society, namely, the increase of open drug shops owned by unqualified persons. It was a well-known fact, he remarked, that the number of pharmacies was increasing out of the usual proportion to the population, and, naturally, registered chemists and druggists were anxious to keep the trade to themselves. But unqualified persons continued to open "apothecaries'" and "medical halls," "laboratories" and the like, with a friendly medical man to come between them and the law when necessary. This was unfair to young men who took the trouble to pass examinations, it was unfair to every registered chemist and druggist, and was very injurious to the public. He would like to see the Society doing something to put down this sort of thing, for as long as it continued it was a slur upon them.

The President of the Branch said that this was a matter which they all regretted, but was one of enormous difficulty to deal with. It should not be forgotten that a medical man was quite within his legal rights in keeping an open shop, and the Society could not, under the present Acts, prevent a medical man or any other qualified person giving the use of his name to an unqualified one. It was the former who was responsible in law, and if he chose to assume the responsibility they might have their own opinions about his conscientiousness, but the existing legal powers could not touch him.

Mr. Borland stated that this was a matter which had engaged the attention of the Council of the Society for a considerable time and he could assure Mr. Murdoch that they were extremely desirous of effecting a change. It might be remembered that the Pharmacy Acts Amendment Bill contained a clause which actually touched these cases. By this clause the Registrar had power to demand the name of the owner of each open drug shop in Great Britain, and it was hoped that this would go a great way to put down illegitimate trading. Unfortunately the progress of the Bill was uncertain, but members could help it on by influencing their parliamentary representatives. If members could suggest any other remedy than the one proposed he could assure them that it would be most carefully considered. Meanwhile they could rest assured that their interests were being constantly attended to by their Council.

Mr. Mackenzie said that there was only one way of putting down this matter, namely, to get a clause inserted in the Medical Acts Amendment Bill to the effect that medical men who kept open drug shops should be qualified according to the Pharmacy Acts. He had every reason to believe that such a clause would be supported by several prominent members of Parliament, and it was well known that leading medical men were in favour of it.

After some further remarks on this subject the report was unanimously adopted.

The Secretary to the Branch then submitted the report of the Committee of Scrutineers on the voting for vacancies in the Council of the Branch, caused by the retirement of fourteen members according to the rule instituted last year. Nineteen gentlemen had accepted nomination for the vacancies. The Committee reported as follows:—

Voting papers issued	272
Voting papers returned	135

Of which *one* was informal.
Leaving 134 papers to be recorded.

After tabulating the votes (a statement of which was laid on the table), it was found that the following gentlemen had a majority of votes:—

Ainslie, William, 58, George Street, Edinburgh.
Borland, John, 7, King Street, Kilmarnock.
Clark, W. Inglis, 26, South Canongate, Edinburgh.
Frazer, Daniel, 113. Buchanan Street, Glasgow.
Laird, George Hardie, 40, Queensferry Street, Edinburgh.
McAdam, Robert, 34, Virginia Street, Glasgow.
Mackenzie, James, 45, Forrest Road, Edinburgh.
Napier, Alexander, 69, South Clerk Street, Edinburgh.
Nesbit, John, 162, High Street, Portobello.
Pinkerton, William. 17, Greenside Place, Edinburgh.
Storie, Robert, 94, High Street, Dalkeith.
Strachan, Alexander, 148, Richmond Street, Aberdeen.
Watt, James, Haddington.
Young, James Robertson, 17, North Bridge, Edinburgh.

The President of the Branch declared that these gentlemen and Messrs. Baildon, Gilmour, Kinninmont, Mackay, MacRitchie, Stephenson, and Storrar (who retain office for another year) would constitute the Council for 1884–85.

Votes of thanks were then awarded to the President, Vice-President, Honorary Treasurer, and Auditors, for their services, after which the meeting adjourned.

As in former years, the new Council met after the Annual Meeting for the election of office-bearers. Mr. Gilmour in proposing the re-election of Mr. John Nesbit, as President of the Branch, took occasion to compliment him on the satisfactory manner in which he had conducted affairs. It was important, he remarked, that a man of experience should occupy the chair during the ensuing year, which would be an auspicious one in the history of the Branch, and he was sure that in Mr. Nesbit they had such an one. He had great pleasure in moving his re-appointment.

Mr. Frazer seconded the motion, and it was unanimously adopted.

Mr. Nesbit accepted office and returned thanks.

Mr. H. Bellyse Baildon, on the motion of Mr. Borland, seconded by Mr. Young, was re-appointed Vice-President, and Messrs. Gilmour and Young agreed to audit the accounts.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 1. Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—H. B. Baker, E. G. B. Barlow, W. F. Fremersderff, J. Hargreaves, F. Nettlefold, J. Parr, A. E. Page, T. Stormouth, J. S. C. Wells.

The following papers were read:—*On Benzoylacetic Acid and Some of its Derivatives* (*Part I.*), by W. H. Perkin, Junior.—For various reasons the author determined to carefully examine benzoylacetic ether with special reference to reactions in which the ketone group takes part. He describes first the preparation of phenylpropiolic acid. Five hundred grams of cinnamic acid are suspended in 1–1·5 litres of absolute alcohol and hydrochloric acid is passed until the whole is dissolved. After standing for two to three hours the product is poured into ice and water. The cinnamic ether separates out as an oil, which is dissolved in ether, washed with a dilute solution of sodium carbonate, thoroughly dried, and treated with 440 grams of bromine. After standing for a short time the whole is poured into a large dish, and the ether allowed to evaporate, when phenyldibromopropionic ether separates out as a solid cake of large crystals. These are pressed between filter paper, and decomposed by alcoholic potash. The potassic phenylpropiolate is finally treated with dilute sulphuric acid when the free acid separates out as an oil. After purification it was obtained in crystals the measurements of which are given. The acid was then converted into phenylpropiolic ether, which, when treated with ordinary sulphuric acid slightly diluted with water, forms benzoylacetic ether. Full details of all the reactions are given. The ether is a colourless oil, boiling at 265° to 270° without much decomposition; it gives the same violet coloration with chloride of iron as aceto-acetic ether; boiled with dilute sulphuric acid it splits up into acetophenone, alcohol, and carbonic anhydride. The hydrogen atoms in the CH_2 group are replaceable by sodium. The barium, silver, copper, and lead salts were prepared. When pure benzoylacetic ether is treated with dilute aqueous potash, and the resulting product decomposed with dilute sulphuric acid, benzoylacetic acid was obtained which, after purification, crystallized in thin transparent needles, which polarize light, and melt at 103° to 104°. The copper, lead, calcium, barium, and ferric salts were prepared, and two analyses are given of the pure acid. In the next part of the paper the author has prepared compounds in which the hydrogen atoms in the methylene group are substituted by ethyl, etc. Thus ethylbenzoylacetic acid melting at 111° to 115° and ethylbenzoylacetic ether were investigated, the latter substance when treated with moderately dilute potash yields much phenylpropylketone, but with strong potash mostly organic acids are formed. The latter part of the paper gives an account of the preparation of diethylbenzoylacetic acid, allylbenzoylacetic acid, the corresponding ethers, their decomposition products, and an investigation of the action of bromine on allylacetophenone.

Dr. Percy Frankland then read a paper—

On the Composition of Coal and Cannel Gas in Relation to their Illuminating Power.—In this paper the author gives the results of his examination, somewhat in detail, of the gas supplied to some of the more important towns of the United Kingdom. The constituents which have been individually determined are the hydrocarbons absorbed by fuming sulphuric acid, carbonic anhydride, oxygen, nitrogen, hydrogen, carbonic oxide and marsh gas. In all cases the carbon density of the hydrocarbons has been determined, and in many cases also the hydrogen density; the carbon and hydrogen densities together representing the average molecular formula of the hydrocarbons present. Details of the determination of these densities are given. The reputed illuminating power and the ratio of the illuminating power to the proportion of ethylene to which the heavy hydrocarbons are equivalent are also recorded. The predominant hydrocarbon seems to be ethylene, but the quantity of this gas present is quite insufficient to account for the illuminating power of the gas. So that the denser hydrocarbons, though present in comparatively insignificant proportions, have much to do with the actual illuminating power. In comparing these analyses with similar results obtained in 1851 and 1876 it is seen that the carbon density has diminished whilst the quantity of nitrogen has increased.

Dr. Armstrong said that in oil gas much of the illuminating power was due to acetylene, crotonylene, etc., and, probably, in coal-gas the illuminating power was due to hydrocarbons of the acetylene series rather than to benzene. He suggested that the sulphur in coal gas, other than hydrogen sulphide, might be due to the presence of thiophene.

The Secretary then read a paper—

On a New Form of Pyrometer. By T. Carnelley and T. Burton.—The pyrometer, which the authors have used since 1881, consists essentially of a copper coil, which is placed in the muffle, kiln, etc., of which the temperature is to be determined. Through this coil flows a constant current of water. The temperature of the water is taken as it enters the coil and as it flows out; from the difference of these two temperatures and a table the temperature to which the coil has been exposed can be ascertained. A similar instrument has been devised by Boulier (*Bull. Soc. Chim.*, xl., 108). By means of the above instrument temperatures up to 650° C. have been determined to within 25°.

The Secretary then read three papers by E. Divers and Masachika Shimosé, of Tokio—

I. On Selenium Sulphoxide.—The authors summarize their results as follows:—A yellow modification of selenium sulphoxide appears to exist, but has not been obtained pure; when heated it is decomposeed into selenium and sulphur trioxide; sulphur trioxide oxidizes selenium sulphoxide, forming selenium dioxide and sulphur dioxide. Tellurium sulphoxide when decomposed by water gives tellurium and sulphuric acid, and by a secondary reaction sulphurous and tellurous acids are formed. *II. On the Reaction between Hydrogen Chloride and Selenium Sulphoxide.*—This reaction may be represented by the two equations—

$$(1)\ 2SeSO_3 + 2HCl = SeSO_3SeCl_2 + H_2SO_3.$$

$$(2)\ \underbrace{SeSO_3SeCl_2}_{\text{Selenium sulphoxychloride.}} + HCl = \underbrace{Se_2Cl_2}_{\text{Selenium selenochloride.}} + SO_2HOCl.$$

Selenium is dissolved in fuming sulphuric acid and hydrochloric acid gas passed into the solution, which slowly deposits drops of a deep red liquid, which is the selenium selenochloride. The mother liquor contains the sulphurylhydroxychloride, which has not yet been isolated. *III. On Selenium Selenochloride.*—The properties, physical and chemical, and an analysis of this substance are given.

Dr. W. R. HODGKINSON then read a paper—

On Fluorene, Part II.—During the fractional distillation of fluorene the author noticed the formation of an orange-red substance. It appeared probable that this body might be an oxidation product. Several kilograms of fluorene, m.p. 100°, were slowly distilled, and the fraction between 280° to 295° crystallized from acetic acid and redistilled; the fraction between 285° and 290° was then passed over a mixture of lead oxide and manganese oxide (5 to 1) in a wide iron tube, heated to the temperature of melting tin. A red solid thus distilled over, but the coloured substance could not be separated from the unchanged hydrocarbons by distillation. A partial separation was effected by boiling the substance twenty or thirty times with 50 per cent. acetic acid, which dissolved out the fluorene. The substance thus obtained crystallized from glacial acetic acid in rhombs m.p. 165 to 170, subliming with partial decomposition and forming a dense red vapcur. The body was oxidized by a solution of chromic anhydride in glacial acetic acid. Two oxidation products were obtained, one crystallizing in pale yellow needles almost insoluble in cold chloroform, melting at 278°, and the other separating in short red needles, melting at 188°, both having the composition $C_{13}H_8O_2$. The author has not succeeded in isolating the red colouring substance; it appears to decompose on distillation even in a vacuum, and is equally soluble with the hydrocarbons it accompanies in the different solvents.

The Society then adjourned to May 15.

SOCIETY OF ARTS.

SOME NEW OPTICAL INSTRUMENTS.

In the continuation of the Cantor lectures upon "Some New Optical Instruments and Arrangements," on Monday, the 5th inst., Mr. Norman Lockyer referred to the refraction and reflection of telescopes. Mr. Thomas Hooke, of York, had increased the aperture from 16 to 25 inches, but the anxiety resulting from introducing this plan led to his death; each lens which he made was tested at his observatory by means of the stars, but afterwards he found that a horizontal well 500 feet long answered the same purpose. The great drawback then to the use of such large apertures was the fact that crown glass of thirty inches diameter could not be obtained. The lecturer drew attention to a telescope of 3 feet aperture combining a minimum of atmospheric current with great freedom and easiness of motion; the polar axis is floated in mercury, and the tube, the rigidity of which is obtained by cross pieces, consists of four T pieces. A telescope of 8 feet aperture with all necessary fittings can be produced in ten months for the sum of £10,000, quite equal to the French 30 feet telescopes, the movable domes belonging to which cost alone £25,000 each. Though the glassworks of the present time are not able to run more than one ton of glass at one time, nearly two tons of porcelain can be reduced to the same state; experiments therefore are being made in Paris for the purpose of solving the question as to the use of porcelain with a glass surface instead of solid glass. The principal improved optical methods relate to the means by which permanent records of the solar spectrum of the stars can be obtained, and also the photographing of the sun, nebulæ and clusters of stars. The greatest difficulties met with are the excess of light in photographing the sun and the feebleness of the rays of light from the stars. Dr. Gadsen has overcome the excess of sunlight by inventing a trap by which a ray is only momentarily allowed to pass through a small slit upon the plate. Photographs taken by this method give a definite view of the sun spots and cyclonic lines on the sun's surface. Dr. Huggins, by focusing the light from a single star upon the plate through the slit for a period of an hour, has obtained photographs of single stars; for this purpose there is no necessity to keep the ray in the exact position the whole time, but should the photograph of a group of stars or nebulæ be required it is obligatory that each star be kept in a fixed position. Mr. Common has devised a method in which a fine platinum wire is kept in the position of bisecting one of the stars by the observer by means of rectangular screws, thus ensuring the fixedness of the other stars. The lecturer showed some photographs of the nebulæ of Orion exposed for periods successively of one, two and a half, four, ten, twenty and sixty minutes, thus as Mr. Lockyer stated, making it possible to learn more concerning the nebulæ of Orion in sixty minutes with nature than in two and a half centuries of human art. So delicate is this method that not only stars invisible to the naked eye are photographed, but with an aperture of thirty inches, stars ·152 of a second distant apart can be separately distinguished. In concluding the lecture, Mr. Norman Lockyer expressed an opinion that the Society of Arts should endeavour to take steps to enable glass lenses and mirrors to be obtained of sufficient diameter and thickness to meet the present requirements of the optician.

A vote of thanks was passed to Mr. Norman Lockyer for the lectures, and also to Mr. Common for allowing his photographs to be exhibited.

Parliamentary and Law Proceedings.

POISONING BY A LINIMENT.

An inquest was held in the Park Hotel, Birkdale, on Tuesday, April 29, before Mr. Samuel Brighouse, district coroner, on the body of Mrs. Large, who died on the previous Saturday, consequent upon taking a quantity of poisonous medicine.

Winnifred Mabel Large, aged between twelve and thirteen years, daughter of the deceased, said that on Friday Dr. Newsham saw her mother, on which day two bottles of medicine in question were brought to the house by her father. Witness did not think she gave her mother on Friday any of the medicine intended for internal use, but on Saturday morning she gave her a dose of it. About noon the same day she went to give the deceased another dose. The two bottles—one containing the medicine for inward and the other for outward application—were on the dressing-room table in her mother's bedroom, and her mother was in bed. The deceased asked witness to give her a dose of the medicine. The bottles were with their flat side towards the witness at the time, and the word "Poison" was plainly visible on the one containing the liniment. Witness took up the right bottle, but then stooped down to pick up something, and when she rose she lifted the bottle containing the liniment by mistake, and gave her mother a dose from it. As soon as her mother had taken the dose she found that a mistake had been made, and said so. Witness then ran downstairs for a neighbour, and Drs. Vernon and Newsham were sent for. Witness had no idea what deceived her, or caused her to make the mistake, when she rose from stooping for something as described. The room was partially dark at the time, the blind in front of the bed being down.

To the Foreman: I knew the difference between the two bottles. I had been told that the one marked "Poison" contained medicine which was poisonous.

To the Coroner: I can read. It was a tablespoonful of the wrong medicine I gave my mother, the prescribed dose of the other being that quantity.

Dr. Newsham deposed: I practise as a physician and surgeon in Birkdale. On Friday I was called in to attend the deceased and found her suffering from neuralgia. I prescribed medicines for her, one of which was to be taken internally, and the other to be applied externally. The bottles produced are those I sent. The poison in the liniment is belladonna, and the bottle containing that medicine is marked "Poison" on both sides.

In reply to a question by the Coroner, the witness said that he informed both Mr. and Mrs. Large of the highly poisonous nature of the liniment.

The Coroner remarked that he noticed the bottle containing the liniment and that in which the medicine for internal use was were similar in shape and size. Would it not have been better to put the liniment in a bottle of another and distinctive kind, so that the shape and appearance, in addition to the label "Poison," would indicate its contents?

The witness said he thought not. His experience was that there was less risk of mistake when the two bottles were alike in appearance, because in that case the label bearing the word "Poison" would always have to be referred to. When the bottles containing the two kinds of medicine were dissimilar in shape and appearance he thought there was more liability to error, as the mind became familiarized with them, and sometimes confounded them, there not being the same apparent necessity to look for the label bearing the word "Poison." In such cases as that in question he always supplied the liniment and other medicine in bottles of the same kind. He knew that as a rule medical practitioners when giving two such kinds of medicine put them respectively in bottles dissimilar in shape, but others did not do so. The liniment bottle in question was a four-ounce one, and for each ounce in it there was a drachm of the extract of belladonna root. There was also half an ounce of chloroform in the preparation. A teaspoonful of belladonna of the same strength had been known to prove a fatal dose even when medical aid was at hand. He was of opinion that the tablespoonful administered to the deceased comprised five teaspoonfuls. When he arrived at the deceased's house after the occurrence in question he knew the case was a hopeless one. He had been in practice for ten years as a qualified medical man. In reference to a remark by the Coroner about putting medicines in such cases as that under consideration in bottles of different shapes, witness was of opinion that in giving the bottle containing a poisonous preparation a characteristic shape the mind was taken away from the poison itself. Besides, it was his custom, particularly with regard to the humbler classes, always to warn them to put the poisonous preparation in such a place as would require a distinct act to get at it—on the top of the wardrobe, on the floor, or some such place.

The Coroner: Is there any medicine you prescribe to take inwardly which would poison the patient if a larger dose than that directed were taken?

Dr. Newsham: There is.

The Coroner: Are such medicines labelled "Poison?"

Dr. Newsham: No; but there are directions on the bottle specifying the dose, and how the medicine is to be taken.

After some further evidence the Jury found that the deceased "came to her death by misadventure;" and recommended "that in future the medical profession distinguish poison from medicine for internal use by putting up the poison in a bottle of a different shape from the medicine bottle."—*Southport Visitor.*

Poisoning by Carbolic Acid.

An inquest has been held at the Manchester City Coroner's Court, before Mr. Sydney Smelt, deputy-coroner, into the circumstances causing the death of Samuel A. Janney, an American planter, aged fifty.

From the evidence of Anthony Nava, the keeper of the Crown Hotel, Great Ducie Street, Strangeways, it appeared that the deceased gentleman was a native of Baltimore, United States, and had been staying at the hotel for about two months. He had been ill for about three weeks, and was attended by Dr. Crean and Dr. Dreschfeld, together with a nurse from the infirmary, named Rossington, in the daytime, and a nurse named Mrs. Holliday at night. On Tuesday afternoon the night nurse relieved Rossington, and about midnight Mrs. Holliday came and told him that deceased was much worse, and he went for Dr. Crean. Witness returned, and found both nurses there saying something about a draught, and they showed him a little bottle which smelt strongly of carbolic acid, and Mrs. Holliday said she had given deceased the draught. There were four bottles of carbolic acid in the bar holding about a pint each. The bottle produced held about two tablespoonfuls. All the medicine used by deceased was kept in his room. The nurse was quite sober. Medicine coming into the house was generally placed at the bar window and sent to the room afterwards.

Susan Rossington, one of the nurses to the deceased, said that she used carbolic as a disinfectant. She left deceased with Mrs. Holliday about half-past three and returned about 11 o'clock, when deceased was sleeping. About half-past 11 Holliday asked if she might give deceased a draught which had just come. Witness replied. "Yes, certainly." About 12 o'clock she was aroused again by Holliday, and on going to deceased's room she found he was dying. The small bottle produced, labelled "to be taken immediately," was on the table, and it smelt of carbolic acid. Deceased died about two o'clock. Witness believed that a draught was given to deceased about a week ago from a bottle very much like the one produced.

Mr. Richard Crean said deceased had suffered from liver disease and jaundice. He prescribed a draught for deceased about ten days ago, but had prescribed nothing since then. Deceased was unconscious when he arrived, and died a minute or two afterwards. His lips and tongue were blotched by some corrosive like carbolic acid, and his breath smelt of carbolic acid.

Mrs. Nava, the landlady, and Elizabeth Ann Beveridge deposed to finding the small bottle in the bar the previous night about 10 o'clock. It was standing amongst other bottles, and was not wrapped up and sealed. Such a bottle had never been used for keeping carbolic acid, and they had kept none recently except to disinfect the deceased's room.

Mrs. Holliday also gave evidence, and Thos. Bateson, the assistant to Mr. Thomas Jackson, chemist, of Great Ducie Street, said that the bottle produced was dispensed by him before the 17th of April, and sent to the Crown Hotel, wrapped in paper and sealed. It contained nothing but bromide of potash and camphor water, and it would be sent away full. That dose had been repeated once, but not this week. No draught was sent on Monday or Tuesday.

The inquiry was then adjourned for the purpose of finding, if possible, who put the carbolic acid in the medicine bottle, but without success, and medical evidence having been given that death had been caused by poisoning by carbolic acid, the Jury returned a verdict to that effect, adding that whether the cause was accidental or otherwise, the evidence was insufficient to show.—*Manchester Courier.*

Obituary.

Notice has been received of the death of the following:—

On the 18th of April, Mr. John Pumphrey, Chemist and Druggist, Bengeworth. Aged 64 years.

On the 26th of April, Mr. Richard Burgess, Chemist and Druggist, Winsford. Aged 58 years.

On the 26th of April, Mr. Richard Brierley, Pharmaceutical Chemist, Market Place, Stalybridge. Mr. Brierley had been a Member of the Pharmaceutical Society since 1853, and for several years filled the office of Local Secretary.

On the 30th of April, Mr. Thomas Bell, Chemist and Druggist, Ambleside. Aged 68 years.

Review.

THE GOLD-HEADED CANE. Edited by WILLIAM MUNK, M.D., F.S.A., Fellow and late Senior Censor of the Royal College of Physicians.*

A conventional dress and manner characterized the physician of a former century; the wig as part of a professional costume came in with Charles II., and continued to be worn long after George III. was king. The cane proper, which was indispensable to a medical practice, had a rounded knob or head, often of gold, sometimes of silver, but in later times generally of ivory. In earlier times the knob was perforated and contained Marseilles vinegar.

The celebrated Dr. Radcliffe, who gave his name to the Infirmary at Oxford, had a cane made of a particular pattern for himself, the shape being what is now called a crutch. This gold-headed cane was inseparable from the doctor, who for many years was President of the Royal College of Physicians; and on his death the symbol of authority passed successively into the hands of Mead, Askew, Pitcairn and Baillie, all foremost physicians of their day.

Dr. Macmichael, the intimate friend of Sir Henry Halford, took an extreme and personal interest in the College of Physicians, of which he was for five years registrar; and he hit upon the idea of making the gold-headed cane relate the history of the medical events which it may have been supposed to witness. Hence the book and the anecdotal sketches of the five celebrities just mentioned.

Dr. Munk brings the record down to more modern date, and contributes notices of Halford, Paris and Mayo; together with a running commentary on things medical; men, however, rather than medicine being described.

It is pleasant to read about Dr. Radcliffe, with his strong common sense and knowledge of the world which stood him in such stead; how he dared against opposition to treat small-pox with fresh air and cooling emulsions; how before the end of his first year in London he gained twenty guineas a day by regular practice, exclusive of fees that would appear fabulous were they not historical; and how Dandridge, the apothecary whom he patronized, died worth more than £50,000. But we have always admired most the story of the conversation said to have taken place between himself and his classical successor, Mead. "What," said Radcliffe, "you read Hippocrates in the original? Take my word for it, when I am dead you will occupy the throne of physic in this great town." Mead:—"No, sir; when you are gone, your empire, like Alexander's, will be divided amongst many successors."

Mead was an accomplished and varied scholar: he studied the nature of the plague which had made such serious havoc; strongly recommended inoculation in case of small-pox at the instigation of Lady Mary Wortley Montagu; altered the treatment of dropsy by bandaging after tapping; and attended the last illness of Sir Isaac Newton. Two most interesting digressions occur in the biography of Mead, the history of the College of Physicians, and that of the Royal Society.

Passing over the three next worthies we come to Dr. Munk's own share in the recital.

Few have more adorned their profession, or have been more continuously successful than Sir Henry Halford, Bart. His family name was Vaughan, but on the receipt of an ample fortune this was changed to Halford according to the terms of the bequest.

His father, Dr. James Vaughan, himself an eminent physician at Leicester, had five sons; he devoted the whole of his annual professional income to their education, and all five in turn became distinguished, and, indeed, remarkable in their several callings. All five rose to independence as soon as their education was completed.

When Halford (he is known now only by this name) came to London to practise medicine he borrowed a thousand pounds and started with that capital; he married a nobleman's daughter, having two years before been appointed Physician Extraordinary to the King (George III.). In seven years he had to resign his position at the Middlesex Hospital owing to the claims of private work; and then his reputation caused him to be consulted by Georgiana, the beautiful Duchess of Devonshire. Her disease was beyond all medical aid, but Halford was proved to have been correct in his diagnosis, contrary to the opinion of the regular physicians of her grace. His professional income rose instantly and largely. During his first year he had realized 200 guineas; in his sixth year the amount was 1000 guineas. Five years exactly after this event he and Dr. Baillie, the other fashionable physician of the day, were posting down to Windsor to visit Royalty. They compared their annual incomes; Halford had made 9500 guineas; Baillie, 100 guineas more. Sir Henry Halford was Physician in Ordinary to four successive sovereigns; almost every member of the Royal family, from the time of George III. to the death of George IV., had been under his professional care. His patients were the Court Guide. He was noted also for his admirable Latinity, his compositions in that language being a study worthy of imitation. By his chief instrumentality, and while he was president, the College of Physicians was removed to its present situation in Pall Mall; and Halford established there a series of evening meetings, which were frequented by the leading representatives of learning, literature, and science.

The author of the 'Pharmacologia,' John Ayrton Paris, has reaped more than passing fame from his fine contributions to medical literature. Strangely enough, his name is subject to a typographical error in the 'Gold-Headed Cane.' Exception may also be taken to the disquisition on solar, telluric and animal heat introduced into this section; it appears to be inserted in the wrong place, and the illustrations are not new.

Dr. Paris succeeded Sir Henry Halford in the Presidential chair of the College of Physicians. His career is specially interesting to the pharmacist from his attachment to chemistry and materia medica; in fact, a predilection for natural science characterized his whole life. Through his influence the Royal Geological Society of Cornwall was established. The safety bar and an instrument called the shifting carriage were said to have promoted the security of the miner as much as the Davy lamp. It was Paris who took an interest in young Faraday and secured for him the credit of having first liquefied chlorine gas. He soon became the most popular lecturer on materia medica in London, and his class was attended by many distinguished physicians of the next generation. In his own department he has had no superior in clearness and power of exposition. His best known work, mentioned already, ran through many editions and realized for its author above £5000. For the 'Treatise on Diet and Regimen,' he received £1000 before a line of it was written; and a similar sum for his 'Life of Sir Humphrey Davy,' when it was finished. Two works came to grief, 'The Medical Jurisprudence,' and 'The Elements of Medical Chemistry.' Here he shared the fate of Sir Benjamin Brodie, whose 'Psychological Studies' were not favourably received. But he made amends by his profits on a little book called 'Philosophy in Sport made Science in Earnest.' Those who would learn how to write the English language can have no better model than the 'Historical Introduction to Materia Medica,' which forms a sort of long preface to the work by which Dr. Paris will be remembered.

Here we must close these notes on Macmichael's 'Gold-Headed Cane' and its continuation by Dr. Munk.

* London: Longmans, Green and Co. 1884. Crown 8vo. Pp. i.-xvi., 1-246. 7*s.* 6*d.*

It is brimful of anecdote, and contains authentic information on the rise and constitution of certain great institutions.

All books of this class deepen our esteem for the acquirements and character of the medical profession; and we may reflect with pleasure, that however distinguished or successful were the physicians of a former date, they have left a race as eminent, to sustain the traditions of the past.

Liquid Extract of Cinchona.

Sir,—In the experiments I made for the purpose of obtaining data on which to found the process I have suggested for liquid extract of cinchona, a sample of succirubra bark was first operated upon which, tested by De Vrij's method with lime and alcohol, yielded 4·8 per cent. of total alkaloids; and this in No. 60 powder, when treated as I have described with hydrochloric acid and water, and reduced to a dry extract, gave by precipitation with soda an amount of alkaloid corresponding to 4·3 per cent. of the bark used. In this operation not only was the percolated liquid acid, but the marc at the end of the process was slightly so also, and viewing this in connection with the fineness of division of the bark and the known action of hydrochloric acid as a solvent of cinchona alkaloids, the result did not exceed what appeared to me reasonable to expect. I took the near approximation of the amount of alkaloids in the extract to that in the bark yielding the extract as indicating a practical exhaustion of the bark, although, no doubt, further evidence would be looked for to establish complete exhaustion, especially as the method I adopted for estimating the alkaloids in the extract is not a rigidly exact one. My object was to devise a method as little complicated as possible and suitable for adoption by pharmacists generally, but the desire to submit such for criticism at a pharmaceutical meeting before the meetings had terminated for the season rendered it necessary to leave several parts of the investigation to be subsequently completed.

Since the publication of my paper I have repeated the process upon further samples of East Indian succirubra bark with results similar to those I have already recorded. The barks I have used have contained from 4·8 to 5·5 per cent. of total alkaloids, and with these I have found that when the percolated liquid has reached a quantity corresponding to ten or, at most, eleven pints of percolate from a pound of the bark, it has ceased to give a precipitate with soda. The marc, on being then treated with fresh hydrochloric acid, although yielding a solution which gives a dark brown extract with soda, some of which may be precipitated, has afforded me no distinct evidence of the presence of alkaloid. By a more searching process, however, with lime and alcohol (De Vrij's method) a small quantity of mixed alkaloids may be extracted, amounting, I have found, to about a tenth part of the alkaloids originally present in the bark, as determined by the same method. Thus a bark containing 5 per cent. of alkaloids, after being exhausted by the hydrochloric acid process, yielded 0·53 per cent. of additional alkaloids, the same method of estimation being adopted in both cases.

The results obtained by Mr. Cownley, and published in last week's Journal, appear to me to be explicable only by assuming that the sample of bark he has operated upon differed very much from any of those I have employed. It was richer in alkaloids than any of mine, but I do not think that alone would account for the results obtained by him. I have not yet worked on barks so rich in alkaloids as the one he describes, but am prepared to find that some modification of the process, especially in regard to the proportion of hydrochloric acid, may be necessary to meet the requirement of very rich barks. I attach importance to the degree of comminution of the bark in treating it by this process, and the fact that Mr. Cownley found it necessary to continue the percolation much further than I have done has raised a doubt as to whether he used the bark in sufficiently fine powder.

T. Redwood.

Spirit of Nitrous Ether.

Sir,—I am sorry to occupy more of your space with a subject which may not be of general interest to your readers, but Messrs. Dott and MacEwan are evidently so extremely irritated at my remarks and appear to have taken such pains to show that they are the only people who know anything about the above subject, and have done this in such a manner, that I feel called upon to reply. Mr. Dott's allusion to what he calls my sneer is calculated to produce an utterly wrong impression. I expressed my disappointment at the papers of these gentlemen because I had expected something very much better from them and from the North British Branch, from which source some of the best and most useful papers which have appeared in the Journal recently have been derived, notably those by Dr. Clarke and Messrs. Gilmour, Aitken and many others. If my expression was taken as depreciatory of the papers which have been contributed—some by Mr. Dott himself—to that Branch, I very much regret it, and I do not think that it was capable of that construction. Mr. Dott seems determined to foist upon me, notwithstanding my denial, an opinion which I neither held nor expressed.

I am content to leave anyone who is interested in the subject to judge whether my words as quoted by Mr. Dott are fairly capable of the construction which he puts upon them.

I am not surprised that Mr. Dott, who no doubt can perfectly account for the respective functions of the various constituents of the sundry acetous preparations so long used, should sneer at the acetic acid having anything to do with their actions; I indeed quite expected as much, and will not further enter into the subject, although Mr. Dott is pleased to call my remarks, "sheer nonsense." Mr. Dott in his paper says, "the only mention I have seen of the use of potassium iodide as a means of estimating," etc., etc., and refers to Mr. Hehner's suggestion of using this reagent with acetic acid; but in his recent letters he speaks of the idea as being in no way new, and says that he only refrained from mentioning my process as he could only have done so to condemn it. Which of these statements are we to believe? I had undoubtedly seen Mr. Hehner's remarks, but had forgotten them entirely, or I should probably have tried the acetic acid which he suggested. The idea is of course such a very likely one to occur to anyone that I did not claim any originality for it, which Mr. Dott certainly does, although he only copies Mr. Hehner's idea, simply substituting sulphuric for acetic acid, adding a little spirit, and adjusting his quantities to give whatever may be decomposed in terms of nitrite of ethyl. Mr. Dott ridiculously accuses me of believing and imagining a great deal too much; but I do not, as he does, imagine that an ingredient forming perhaps one fifth of the peculiar principles of the preparation is the only one worth estimating.

In reply to Mr. MacEwan's letter, I must admit that I did write two months for three weeks, but the matter is of no moment.

Mr. MacEwan then proceeds, with a politeness even surpassing that of Mr. Dott, and an assumption of wisdom quite pleasing, to state that I have neglected to take account of a certain elementary chemical fact; but he seems to forget that he admits in his paper the fact to which I alluded, and the only difference between us is one of degree.

He says that "the method is certainly not free from objection, the sources of error being (1) decomposition—

that is, further acidity." If for the words "the method is not free from objection" he had written is "worthless" I should have agreed with him. It is unfortunate for Messrs. Dott and MacEwan, who unite in heaping contempt upon me, that their results, as pointed out by Dr. Clarke, by no means agree.

Mr. Dott's figures are equally at variance with those of Dr. Dupré, who found by his process, which, like Mr. Dott's, includes free nitrous acid (and which, he admits, over estimates), only about half what Mr. Dott has found.

In conclusion, I may say that any reaction peculiar to a substance and which is capable of being measured forms, so far, a means of estimating it, and in this way neutral iodide of potassium does, without any acid, enable the B.P. preparation to be estimated. That this reaction is not only dependent upon the acidity is proved by the fact that spirit of nitrous ether when fresh liberates more iodine than it does after keeping.

When, as Professor Attfield says, we do not know what sp. æther. nit. is, it is surely better to rely upon a reaction which the preparation shows than to theorize and found a test upon your theory. A. C. Abraham.

[*** We would suggest the desirability of avoiding the tone of personality which the correspondents on this subject seem inclined to assume.—Ed. Pharm. Journ.]

The Antipodes.

Sir,—My attention has just been directed to a request by "Inquirens" for information as to the prospects of pharmacists at the Antipodes.

Eight years ago I was in Melbourne, and present at the first annual dinner of the Pharmaceutical Society of Victoria, and had then an opportunity for speaking on some of the subjects referred to in "Inquirens'" letter. I stated, that from what I had observed respecting the arrangements and conduct of colonial pharmacies, I had no hesitation in expressing my opinion that they were generally excellently appointed establishments, and some of them equalled, if not surpassed, many of our leading pharmacies at home. In fact, in the larger cities and townships, notably Melbourne, Ballarat, Sandhurst and Geelong, in Victoria; Adelaide, in South Australia; and Sydney, Bathurst, Newcastle and Maitland, in New South Wales, pharmacies were to be met with that would not be out of place here, in Oxford Street and Regent Street; I told them they followed us so closely that when walking up Bourke Street, or through Collins and Swanston Streets, Melbourne, "doing the block" as they call it, it was difficult to believe, and hard to realize the fact of being over sixteen thousand miles away from London. As the only representative present of the parent Society, and as a Founder of that Society, I was invited to give my impressions of pharmacy in Victoria, and I remarked that whilst I was astonished at the evidences of advanced pharmacy everywhere observable, I feared they were following us almost too closely, as they had evidently got into some of our bad habits, for I observed they kept open their establishments until 10 o'clock p.m. and even later on Saturday nights, which I thought could not be a necessity, but on the contrary was a very great mistake.

From a notice in this same Journal of April 12, under the heading of "Pharmacy in Victoria" I regret to learn the long hours system still continues; but an effort is now being made by the Chemists' Assistants' Association to bring about a slightly improved state of things, and I wish them all success, trusting it may lead to something better still.

In reply to the question "Would it be better to take situations as assistants, or start at once on our own account?"—I have no hesitation in advising the adoption of the first course. Get into some good pharmacy for a year or two; it will not be lost time, you will be getting acclimatized and experienced, and be able to look about you before settling down.

The leading pharmacists there, as here, object to engage assistants who merely seek their own interests, and expect at least a two years' engagement.

Qualified assistants, with good testimonials, run no risk of failing at once to meet with first-class engagements and liberal remuneration for their services; but let there be no mistake, there must be the *quid pro quo*.

The man who would not make his way at home is not the man to emigrate; he will utterly fail in the colonies.

Before settling down to a business on his own account I would recommend "Inquirens" to take a trip to New Zealand, as Dunedin, Christchurch, Wellington and Auckland all present most favourable opportunities as centres for observation and experience, and the climate generally is more adapted to the English constitution.

My impression also is, that there are better chances for commencing business there, than in the larger Australian cities.

Hawking Chemists and Cutting Prices.

Sir,—I am glad to see a letter in your last issue on the above subject. To my mind it is sad to find that after all the efforts put forth to elevate the position of chemists in this country we find it a fact in the year 1884 that some members of our trade or profession (?) should stoop to such mean practices as to hawk their goods about, and also to solicit orders from door to door, and that sometimes in a most offensive manner. I am not quite sure in a case lately reported if the parties are not breaking the law by not taking out a pedlar's licence, too. Cutting shops and their doings have been freely discussed in your Journal, and in this free country I do not see any good remedy has been proposed to stop it. The only chance the future chemist will have is by bringing to bear his higher education and professional ability that he may gain public recognition. I am not qualified by examination, being one of the older members of the trade, but, nevertheless, qualified I hope by long experience. I positively admire and respect the man who modestly holds the Major certificate of the Society; but the man who just struggles through the Minor and then announces to an astonished world that he is a chemist and druggist by examination should be treated as a humbug by all who would see this trade raised to its proper status.

Cutting prices have frequently been brought about by the grasping characters just alluded to; not content with their own business they press hard upon the heels of some 'cute grocer, who, in revenge attacks the legitimate goods of the chemist.

I see no help for it but the powerful influence of the trade through the Society being brought to bear upon such individuals until they are perfectly ashamed of their caravan drug carts and druggists' shops on wheels, etc. When a member of the medical or legal professions bemeans himself he soon loses caste. Why should it not be so with chemists?

A Northamptonshire Chemist.

Herbalist.—(1) *Euonymus europœus.* (2) *Petasites vulgaris.* (3) *Lycopus europœus.* (4) *Tamus communis.* (5) *Solidago Virgaurea.* (6) *Carpinus Betulus.*

WARAS.

BY W. T. THISELTON DYER, C.M.G., F.R.S.

Perhaps I may be allowed to add a few remarks to what is stated about "waras" in Mr. Kirkby's interesting paper in the last number of the *Pharmaceutical Journal.* The note contained in the inclosed copy of the 'Kew Report' for 1880, p. 50, is, I believe, the origin of the identification of the plant producing the Aden drug with *Flemingia congesta.**

Professor Flückiger, with whom I had corresponded upon the subject, informed me (July 12, 1881) that though he at first objected to *Flemingia* as the source of "wars" he then thought the statement correct.

As the Kew Museum contained no satisfactory specimens of either African or Arabian "waras," we applied to the Resident at Aden to kindly assist us in procuring samples. These reached England in July of last year. In both cases the "waras" itself agreed microscopically with an authentic sample derived from Professor Flückiger, and had the structure figured by Mr. Kirkby. All three also exhibited the characteristic property of turning first bright red, then black, when carefully heated in small quantity on a glass slip over the flame of a spirit lamp.

The sample of Somali "waras" was mixed with seeds of a dull brown colour mottled with black. These were found to agree precisely with the seeds of *Flemingia rhodocarpa*, Bak., from the Mozambique, which, as mentioned in the 'Kew Report' (*l.c.*), "has its pods covered with a bright red resinous pubescence." A further scrutiny of the original specimen obtained by Captain Hunter from the neighbourhood of Aden, which is in a rather immature state, led Professor Oliver to the conclusion that this also belonged to *Flemingia rhodocarpa.* I believe that the drug is derived from the young pods and am disposed, therefore, to think that Dr. Dymock is in error in describing it as "the gland of the leaf."

I communicated these further facts to Professor Flückiger, and he wrote to me, October 4, 1883, "I am very much pleased with your statements and can only say, that I most fully agree with your conclusion as to the identity of the Somali 'waras' with my original specimen and also that of the seeds of *Flemingia rhodocarpa* with those met with in the said drug."

In the new 'Official Guide to the Museums of Economic Botany at Kew' (No. 1, p. 45) we accordingly state that "waras . . . . consists of the epidermic glands of the young pods of *Flemingia rhodocarpa*, Baker, native of Arabia and East Tropical Africa."

The third variety described by Mr. Kirkby is quite new to me and I join with him in hoping that some further information about the plant yielding it will soon be forthcoming.

* The following is the note referred to:—

"*Waras.*—A drug known under this name appears to be exported in considerable quantity from Aden. It is used as a substitute for kamala, a well-known Indian product of *Mallotus philippinensis* (*Rottlera tinctoria*, Roxb.). Its origin is quite unknown (*see* Flückiger and Hanbury, 'Pharmacographia," pp. 575, 576). At the suggestion of the former, Captain Hunter, Assistant Resident at Aden, obtained specimens of the plant stated to yield waras in Arabia. He has also sent one to Kew with a note stating that it was gathered 'at an elevation of 6000 feet on Jebel Dthubarah, 60 miles due north of Aden.' The plant sent was immediately identified with a leguminous species, *Flemingia congesta*, Roxb., having of course no affinity with *Mallotus philippinensis.*

"True kamala consists of the epidermal glands detached by brushing from the fruits of the *Mallotus.* Alcohol extracts from it a splendid red colour. The name 'waras' means saffron, and it may be mentioned in support of the notion that a similar substance is yielded in Arabia by perhaps one or more species of *Flemingia*, that dried specimens belonging to this genus stain paper in the herbarium a bright yellow colour when washed over with the alcoholic solution of corrosive sublimate used to protect them from the attacks of insects. *Flemingia rhodocarpa*, Bak., from the Mozambique district has its pods covered with a bright red resinous pubescence.

"In the 'Pharmacographia' (2nd ed., p. 372), Flückiger and Hanbury state that *Mallotus philippinensis* grows in Abyssinia and Southern Arabia. In a letter, Professor Flückiger doubts whether he and Mr. Hanbury were not mistaken in regard to this. The evidence of specimens in the Kew Herbarium only carries the distribution to the west as far as Scinde. There is nothing improbable in its extending to Arabia, the flora of which is still so imperfectly known."

CODEINE HYDROBROMIDE.

BY D. B. DOTT.

Codeine is the strongest of the opium bases, replacing all the others in solutions of their salts. Yet, probably for more than one reason, the salts of codeine are not much in demand, the alkaloid itself being more generally used. As the hydrobromide is sometimes required, I thought that a note of its principal properties might be of some interest, especially as the salt has not been previously described, at least so far as I have observed.

Codeine hydrobromide crystallizes from an aqueous solution in radiate tufts of four-sided prisms. The solubility in water was determined by digestion at a temperature below 60° F. for twenty-four hours, then at 60° for two hours, when portions of the solution were weighed and evaporated to dryness on a water-bath.

a. 165 grs. solution left 1·93 grs. = 1·97 grs. 2 - hydrate.

$$\frac{165-1\cdot97}{1\cdot97}=82\cdot75.$$

b. 144·25 grs. left 1·70 = 173 grs. 2 - hydrate.

$$\frac{144\cdot25-1\cdot73}{1\cdot73}=82\cdot38.$$

The solubility in water at 60° F. is, therefore, approximately 1 in 82·5.

With the heat of a water-bath 8·04 grs. of the air-dry salt lost 0·17 gr. = 2·11 per cent. $C_{18}H_{21}NO_3.HBr.2H_2O$ = 2·16 per cent. for $\frac{1}{2}$ H_2O. In the air-bath at 115° C. 5·74 grs. lost 0·485 gr. = 8·44 per cent. $C_{18}H_{21}NO_3.HBr.2H_2O$ = 8·65 per cent. for $2H_2O$. It is, therefore, evident that the hydrobromide like the hydrochloride loses a fourth part of its combined water at the temperature of the water-bath, and the remainder at some temperature above 100°. But we must not deal in fractions of molecules, so we ought to write the formula $(C_{18}H_{21}NO_3.HBr)_2$, $4H_2O$, or more accurately (having in view the researches of Dr. Wright), $C_{36}H_{42}N_2O_6.2HBr.4H_2O$. We may, of course, use the empirical formula when more convenient, just as we sometimes write the erroneous expression $FeCl_3$ instead of Fe_2Cl_6.

THE CHEMICAL PHARMACY OF THE NEW PHARMACOPÉE FRANÇAISE.

(Continued from page 900.)

This section forms the second part of the Codex Medicamentorius; distinguished by the blue edging of the leaves; the preparations being arranged like the preceding in alphabetical order, the acid radical in compounds being put first and in the vernacular.

The list includes mineral and organic substances, as they occur native, or in a purified condition; metallic bodies and their salts; certain miscellaneous substances, including amber (succin), coal-tar (goudron de houille), and petroleum (pétrole d'Amérique). When possible their formulæ, with indication of their Equivalent and Atomic weights, are given side by side.

In many cases the mode of preparation has been subjoined, omitting for the most part manufacturing commercial processes, though the rule has not been rigidly observed. The larger chemicals have their distinctive characters and properties described. Calomel (protochlorure de mercure) and benzoic acid: as well as similar preparations on the large scale hold their place amongst such chemicals as can or ought to be furnished by the pharmacien; if so, French pharmaceutical chemistry must be credited with higher laboratory work than prevails in England. Foreign criticism enlarges on this point, especially when discussing the elaborate directions given for the manufacture of essential oils, which would hardly be undertaken by the average retail pharmacien.

The fault is on the right side, and should these directions prove useful to those for whose benefit they are intended, they are to be congratulated on their advanced position.

Tests of purity are given when required, and possible adulterations noted; substances deemed poisons are specially marked as such.

The alkaloidal strength is stated in case of salts with organic bases for the guidance of the medical profession. Various chemical products, no longer used in medicine, have been eliminated; while about eighty new substances have been introduced.

As already a revision of the published text of the new Pharmacopée is under the consideration of a Committee, headed by M. Petit; it will be needless to specify the exact relation which the Codex of 1884 bears to its predecessor of 1866. The intention contemplated in this notice is to bring forward such official preparations as are in themselves distinctive, and a knowledge of which may be of service to the English reader.

The introduction of salicylic acid and some of its salts; of ésérine; chloral; chloroform newly described and its characteristics mentioned in detail; iodoform; the sulphates of cinchonidine and quinidine; pilocarpine; the tannates of pellétiérine (a tænifuge) and quinine; and notably of certain bromides and bromhydrates, may, however, be enumerated.

Three terms in constant use must be understood.

Aq=aquâ means always water of crystallization. Thus, carbonate de soude pur cristallisé:—

CO_2,NaO; 10 aq. in French equivalents = 143

or expressed by

$CO_3Na_2 + 10\,H_2O$. F. atom (formule atomique) = 286.

Readers who wish to work out the equations contained in the Codex must consult the table of Corps Simples (Elementary Bodies) printed on page 25 of the Notions Préliminaires.

It will be noticed throughout that two systems of Notation are used; the one based on the equivalent system, *i.e.*, 1 part of hydrogen by weight unites with 8 of oxygen to form water; the formula becomes HO and the combining weight of oxygen 8. The other system is based not on analysis pure and simple, but the combining weights regulated by the laws of specific heat, and vapour density; in fact, the atomic weights as usually recognized in England. In the first, hypothesis is ignored, whereas the second is entirely dependent on it.

A straight line drawn through a symbol marks dyad relation in the printed formulæ.

Altér. = Altérations. Foreign substances which a product may contain owing to incomplete purification. When these are indicated by italics, substances most frequently occurring are designed.

Fals.=Falsification. Foreign substances fraudulently introduced. The term corresponds to our word adulteration.

While in the list of materia medica an asterisk is added to such substances as should be found in every pharmacy, the pharmacien is left to his own discretion in the subsequent sections; a matter of little importance regarding chemicals, and of none in the galencial department, since the preface states authoritatively that it contains such official remedies as should always be in readiness for the prescriber.

Amongst important additions sundry applications of bromine and hydrobromic acid deserve attention. French critics are warm upon the subject of the circumflex accent being placed over the bromine compounds, as Brômure de Potassium in the text, though Brome itself appears without. This printer's arrangement is not invariably adhered to, as may be seen in the general index. Littré is dragged into the argument, and our neighbours must settle their own orthography. Judging from etymology we should pronounce the Codex in the right, and both Chrôme and Brôme have the circumflex in the table of Corps Simples, both having the same Greek authority.

Hydrobromic acid is ordered both gaseous and in solution. The acid is prepared by the action of bromine on melted paraffin; and it can be used directly as gas, or passed into water at 0° when the solution will contain about its own weight of gaseous acid. The solution can be made by acting on dilute sulphuric acid by crystals of bromide of barium; or by passing the gas into distilled water to a density of 1·077, a 10 per cent. solution is obtained.

The hydrobromates are eight in number; that of ammonia corresponds to our ammonium bromide.

The *Bromhydrate of Cicutine* is prepared by passing hydrobromic acid through an ethereal solution of cicutine. The salt being insoluble in ether is precipitated as pulverulent and colourless crystals, which are collected, further washed with ether and rapidly dried. The salt is purified by spontaneous evaporation from a cold saturated solution. One hundred parts contain 61·06 cicutine.

Bromhydrate of cinchonidine (basic) is made by acting on basic sulphate of cinchonidine with bromide of barium and boiling distilled water. Wash out the sulphate of barium; evaporate and crystallize.

Bromhydrate of cinchonidine (neutral) is so rendered by means of dilute sulphuric acid.

Eserine (the process of its extraction from Calabar bean being given in detail) forms one of the bromhydrates. It is simply dissolved in hydrobromic acid, sufficient being added to effect a perfectly neutral solution. Evaporate over a water-bath to a syrupy consistence, and allow it to crystallize for some days. The salt thus made is in fibrous masses, usually of a reddish-yellow colour, and not deliquescent though very soluble in water.

Sulphate of Eserine is also official; made by treating an ethereal solution of eserine with a 10 per cent. dilute sulphuric acid. The salt is directed to be collected and dried by spontaneous evaporation. This method of drying does not seem in keeping with the sentence which immediately follows. "The sulphate of eserine thus obtained is amorphous. It can be crystallized, but with difficulty, on account of its extreme deliquescence." Eserine, as is well known, contracts the pupil.

Of the remaining bromhydrates that of morphine is a simple solution in the acid in hot water. Evaporate over the water-bath and crystallize out the salt, using as drying agents concentrated sulphuric acid, or dry calcium chloride. Solubility in cold water 1 : 25.

The *bromhydrates of quinine*, basic and neutral, call for scarcely any remark. Bromide of barium, being converted into a sulphate, is washed out; and the soluble salt is evaporated and crystallized. In the neutral bromhydrate, dilute sulphuric acid is employed.

Monobrom camphor, and the bromides (bromures) of lithium, potassium and sodium are included in the bromine series. Lithium carbonate and citrate are also official.

It will be well to recollect that brômure ferreux (bromide of iron) is not a solid salt, but a solution containing one third of its weight of ferrous bromide. This must be borne in mind by the English dispenser when making pills of bromide of iron according to the Codex. The matter will claim attention when treating on the galenical section.

It should be stated here that the word "officinal" attached to a preparation generally indicates, and always in the case of acids, that which has been made or purified for medicinal use. Thus we get commercial sulphuric acid, and the officinal, which is the former in a pure state. Hydrocyanic acid is HCy; but a centesimal solution, under the name of acide cyanhydrique dissous, au 100^{e}, the process for its manufacture being given in detail, is the "officinal" or the one to be used in medicine.

Acide phosphorique officinal is the solution made by acting on red phosphorus by nitric acid. By officinal, therefore, is not only meant that the substance is ordered by authority, but that it is presented in the form in which it may be therapeutically exhibited.

The progress of pharmaceutical chemistry has necessitated the introduction of *salicylic acid*, and we find the *salicylates of lithium*, *quinine* (basic) and of *sodium*. To make the second, salicylate of sodium is dissolved in water, and to the solution, boiling, the sulphate of quinine is added. The insoluble salicylate is washed and dried, and carefully tested for absence of undecomposed sulphate.

Acide sulphydrique dissous, a solution of sulphuretted hydrogen, occupies a prominent position, though the English pharmacist would rather assign it a place in a purely chemical treatise. It is directed to be prepared, many necessary precautions being observed, by acting on powdered sulphuret of antimony (Sb_2S_3) mixed with sand, with commercial hydrochloric acid. Gentle heat is to be applied when the action flags or is less energetic. Otherwise a cold process is employed. The gas may be conveniently passed into a mixture of four parts water and one part glycerine, to retard decomposition on exposure to the air.

Permission is likewise given to prepare sulphuretted hydrogen either by acting on protosulphuret of iron by $HCl + 2H_2O$; or by $H_2SO_4 + 8H_2O$.

A useful note is appended to sulphuric acid. The commercial article obviously should be restricted to external use on account of the lead and arsenical compounds it may contain. When this impure acid is rectified on an extensive scale, avoid the choice of larger retorts; multiply their number.

Acetic acid (1·060) replaces distilled vinegar in the obsolete Esprit de Mindérer. Acétate d'ammoniaque liquide (liquor ammoniæ acetatis) is now made by mixing distilled water and acetic acid with the aid of a gentle heat; sesquicarbonate of ammonia is added until feebly alkaline. No water appears in the formula of 1866; the result is otherwise the same.

Acide azotique is not a synonym, but in all the glory of an official title reappears and indeed supplants that of nitric acid. Not that the latter was ever entirely banished, for though rejected by pharmacy, chemistry retained its services. We had thus in olden times acidum nitricum officinale with the formula $AzO_5,4HO$, and nitrate d'argent with the formula $AgOAzO_5$. According to new directions we must read azotic acid, with its salts the azotates.

Eau Régale (*Aqua Regia*).

is thus made:—

Acid. nitric pur.	4
Aq. destillat.	1
Acid. hydrochloric. pur.	15

Mix the nitric acid with the water; add the hydrochloric acid, and keep in an unstoppered bottle for some days.

Benzoic acid, both prepared by sublimation or by the wet process is minutely described with full details of manufacturing process. Neither need occupy attention, as the methods indicated are not likely to be followed by English pharmacists.

The benzoates are made by neutralizing solutions of alkalies with benzoic acid and subsequent crystallization.

In this manner the benzoates of ammonia, lime, lithium and sodium are formed.

(To be continued.)

SCANDINAVIAN PHARMACY.

ADAPTED BY JOSEPH INCE.

(*Concluded from page* 760.)

We must now see whether the laboratories, botanical gardens, and collections of natural history are in keeping with the programme which is sufficiently exacting.

By good fortune Monsieur Labonne was able to inspect them in the completest manner, and he pays incidentally a just tribute to the hospitality of these "Frenchmen of the North."

One day when with some friends he was visiting the ancient cathedral of Upsala, a young law student came up to them and said in the best French he could command, "Will you let me act as guide? Unfortunately I have never travelled in France, and have only learnt French in our academies; I shall be happy to speak with you for practice and see how many faults I make."

Monsieur Labonne having informed him that he himself was a pharmacien from Paris, and also a medical student, the friendly guide proposed to introduce him to two other students of pharmacy and medicine. No sooner said than done. In company of these two the party went to visit the pharmaceutical collections. Professor Frietz, M., took them everywhere. He is a professor of Botany who enjoys the same reputation in Sweden and even in Germany, as Professors Chatin and Baillon do in France. First they inspected the Botanical Garden, the plants being arranged according to the system of Linnæus; then the rooms which are so well arranged for vegetable micrography; and lastly the hot-houses of which the people of the North possess the secret. They delight in having tropical plants in a climate of ice. Amongst other things a mulberry tree was observed planted by Linnæus's own hands. The Swedes reverence their compatriot and are proud of him. A monument has been erected to him in the cathedral; it is a pyramid of porphyry bearing a bronze medallion portrait with this inscription—"Carolo Linné botanicorum principi amici et disciputi. 1798." The house also was shown which he inhabited when he was Professor at the University of Upsala.

The laboratories of physics and of chemistry are likewise irreproachable. One can judge of the general instruction of the country from the following episode:—The law student knew quite as well as the party he conducted, the names of all the plants met with on their walks. A Paris student of law would scarcely be expected to know as much, and perhaps not even a medical student. The plants are with few exceptions the same as in France; only for the same species the colours differ strikingly, for example, in the larkspur. Certain flowers, much neglected in France, are much used in Sweden and Norway.

First must be cited *Epilobium hirsutum*, whose lovely red petals form the background of the marvellous beauty seen in the immense meadowland of Sweden, those fertile and flowery meads. It attains the height of more than a yard, or yard and a half, and dominates the rest. Its bright colour, slender stalk and abundance, arrest the attention of the traveller. One is sure to find it on the way, and it is so faithful a companion that it is met with as far as the arctic circle. The peasants utilize it as food; they drag it out of the ground with the least possible injury to the roots. These roots are dried on hurdles during fine weather, and in the winter vary somewhat their poor vegetables.

Beyond the arctic zone there is a species of sorrel which serves the same purpose.

Oxyria reniformis. It is preserved by congelation; later on, when wanted, it is converted into a pulp by boiling.

The Lapps to keep themselves from scurvy use a very bitter plant, the *Mulgedium alpinum.* They mix it with their bread steeped in reindeer's milk. This kind of pottage must be particularly esteemed, for the day when Monsieur Labonne paid them a visit in one of their chief camps near Troms, he was offered some and was placed on the Boasso. This is a great stone near the hearth, and is the seat of honour in the smoky hut. The *Mulgedium* turned out as bitter as Gentian.

Another plant found in great abundance is the meadow-sweet (Ulmaire). The air in this cold climate is literally saturated with the odour of its numerous white flowers, to the inconvenience of the traveller. Norway and Sweden confirm the law, that flowers of the same species have more perfume in the north than in the south. The extreme solar radiation volatilizes the odorous principles. Everyone knows that in France flowers exhale the least odour in the middle of the day. The sweet scent of the lime trees struck the party. The walks of Christiania are thus perfumed. There is nothing similar to this in the south of France.

It is also very curious to note the rapidity with which certain species belonging to southern regions develop far in the north. Thus planes, *Acer platanoides*, transplanted from Christiania to Troms (70° N.), become extremely vigorous; their leaves are much broader, and their branches much more numerous. It would be very interesting to study with care the effect produced by *a day of several months without a night* on the colour of flowers and the taste of fruits. Such researches have never been undertaken; unfortunately a long residence in these countries would be required.

The *Vaccinium uliginosum* will exhaust the list of plants not utilized in France for food, but precious in that respect in these regions.

Monsieur Labonne first saw this small shrub on the railway. One afternoon on the way to Christiania, little boys, with bare feet, darted out from the depths of the fir woods, and threw handfuls of small green branches at the driver of the train. This was several times repeated and the driver caught the bunches with extreme dexterity. Asked for an explanation, he laughed and bit the small blue berries between his teeth with great gusto. They seemed quite appetizing, especially in a country where there were no grapes, and where one had to regret somewhat the leeks of Egypt, that is to say the fine rich fruits of France. The berries had a rather agreeable acidulous taste, reminding one a little of the grape. The leaves quite resembled those of uva-ursi, which is a broad hint for those who practise adulteration. It was not whortleberry but the *Vaccinium uliginosum.* The shrub was met with everywhere, even at the North Cape, and the berries served to assuage thirst. It was too abundant for it formed the seasoning of all kinds of sauce for fish and flesh.

On the shores of the Arctic Ocean this plant is the sole representative of a scanty vegetation. There, better than the busserole, it deserves the name *bear's grape*, for it literally forms the chief sustenance of that animal in these parts. After this slight digression into botanical details the fauna of Scandinavia must be noticed; and some products special to the country.

The reindeer (*Cervus tarandus*) is the first animal which presents itself to view. The name is from a Swedish word denoting either cleanliness or swiftness, for *rheen* signifies, clean and rānna, means to run. At the present moment the animals are seldom met with wild, but they are seen in droves under their owners' charge. Near Tromsö from five to six hundred were encountered together in one valley. To enjoy this sight previous notice must be given to the Lapps; else there will be very few to show, the main herd being sent to feed upon the mountains. The Lapps who have been demoralized by contact with civilization, demand thirty francs for thus assembling their herds, alleging a pretended loss. This tax must be paid to curiosity. Reindeer milk is very thick, and loaded with butyraceous principles. Its taste is somewhat sharp and biting and it can only be drunk in a diluted state. These animals make a strange noise with their knees. On coming near them, a series of cracking sounds are heard similar to those produced by an electric battery.

In summer their ordinary food is the Vaccinium already mentioned; in winter they live on a small white moss, extremely delicate, which they find beneath the snow by making a large hole with their fore-feet.

They often kill with a blow from the hoof a small rodent, the *Lemus Norvegicus*; not to feed upon its flesh, but to eat the grass which it has in its stomach. This shows a keen power of scent, and proves that necessity is the mother of invention. The Lemus resembles a water-rat.

To find the reindeer wild one must penetrate as far as Spitzbergen; that involves a six months' sail amongst the icebergs. Monsieur Ch. Rabot, well-known for his travels in Lapland, and a member of the Geographical Society, reported to the writer that he had himself killed twenty reindeer. While the seal is attracted by noise, the greatest silence is indispensable when hunting reindeer, and the windward side must be avoided. Frequently fishermen are seen arriving in little boats with some hundreds of these animals on board. These bold sailors brave innumerable dangers to catch the young white bears, which they sell to the different museums.

The grey bear is common. At Throndjem it is a constant dish at a restaurant; but tourists do not like it much on account of its highly flavoured taste.

The lynx and glutton are found. A Government reward of 35 francs is offered for the destroyal of either of these two.

Lastly, there is the *Cervus alces*, a stag larger than a horse.

We come now to the bird kingdom, creatures which exist in fantastic abundance in the arctic circle, and specially in the Lofoden isles.

After the splendour of the scenery, and the strange effects of the midnight sun, that which remains stamped upon the memory by a voyage along the Northern shores of Norway is the recollection of the myriads of winged creatures which form a cloud round the vessel.

You should see them on retiring for the night, battle for a place on a reef just peeping above the water.

You should hear them shrieking one to the other and making an indescribable uproar.

The Eider (*Anas mollissima*) is the most valuable. Its down, says Professor Guibourt, makes furs, muffs and coverlets as warm as they are light. This down constitutes a considerable source of revenue to the province of Finmark. The Dutch trade in the eggs. In Texel these are made into omelettes; and the southern part of that island is called Eyerland (or egg-land), on account of the number of birds which come there to lay their eggs. There is a sale for them at Amsterdam. Proper to Scandinavia are the *Tetrao urogallus*, and the *Laggopus mutus*.

If we pass the wonderful Lofoden islands, and continue the route towards the north, we arrive at Hammerfest, where we quit the birds for the fishes.

As for the city itself, imagine a town watered by cod liver oil and you will have some notion of the odour. The captain had warned the party beforehand, but their handkerchiefs steeped in eau de Cologne were but a slight defence. This horrible smell is due both to the important manufacture of the oil and to the thousands of fish on hurdles drying in the sun.

The two to three thousand inhabitants of Hammerfest, the most northern town in the world (71° N.) are all occupied in this trade. Suffice it to say that a single boat well equipped, well stocked with bait, and in a good place can take from 500 to 600 cod a day. The scientific estimate that the ovary of a female of ordinary size contains nine million eggs.

This is the mode of preparation.

First they remove the head and abdominal viscera; the ovary serves for bait; the liver yields the oil. Not long ago the heads were wasted; now they are dried and powdered and used as manure for poor land.

The body, dried, hard and rolled in sticks, is called stockfish which is imported chiefly into Greece, Italy, France and Spain.

The fresh livers are piled in barrels, slightly pressed, and the virgin oil runs out, unfortunately a kind rare in pharmacy, though its quality is beyond doubt superior. Then the livers are treated by a press similar to those used in Normandy for cider.

This is oil, second quality; colour, reddish-brown.

The waste livers are subjected to strong heat, and an oil is produced, third quality and black.

Whales afford an industrial occupation at Hammerfest.

The day before the arrival of Monsieur Labonne, the fishermen had caught a whale without trouble. The creature had stuck in a small creek which made a sort of natural trap, and it was unable to regain the open sea. The captain was asked what might be the value of the fish; and he replied 6000 crowns (£336). They begin with selling rather dearly the 600 or 700 fins or whalebones; then they make great profit out of the immense quantity of fatty matters contained in the huge creature. This fat, improperly called oil, is naturally liquid and is used for dressing skins. Beside the oleine, margarine, and phoceine, there is a volatile principle of the odour of leather which gives the latter its characteristic smell.

Turning to quite a different train of ideas, there is a monument at Hammerfest erected to the memory of Struve, who measured an arc of meridian from Ismäil on the Danube to the frozen Ocean precisely at this spot.

Further north all cultivation disappears and tree vegetation ceases—nothing but an underwood of stunted birch and willow.

The weather, which had been superb, changed; the wind rose and a tempest broke over the travellers. Fortunately, the dense mist by which they were surrounded cleared, and some hours after they arrived in face of the old rock which marks Cape North. To their surprise the crevices were filled with vegetation. Mosses, dwarf arbutus, saxifrage, houseleek, yellow sedum, and other plants with which they were unacquainted, conveyed an idea of fertility.

Fish, even the largest, is caught with extreme ease; the large red hooks are scarcely plunged into the water than up comes an inhabitant of the sea, not a miserable specimen, but weighing some pounds at least.

Monsieur Labonne then mentions the famous hydromel, which is a syrupy alcoholic liquid made with water, honey and bitter herbs. Formerly it was the national drink of Sweden and Norway, but it has been dethroned by German beer. They tasted it, however, in a very small village near Upsal at Gamla-Upsala. Every visitor makes a point of so doing, and the liquor is served in the hollow ox-horn like that which served for a drinking vessel in the days of Thor, Odin and Freyr. But now they are mounted in silver, and the one offered to the tourist was a gift from Bernadotte to the innkeeper. A metal band bears the names of various princes and princesses who have imbibed the hydromel. The three gods, or rather deified kings, named are interred here, the tumuli being the sole curiosity of Gamla-Upsala. The village church is interesting as containing the tomb of Anders Celsius, the inventor of the centigrade thermometer employed in France. He was a Swede, but the Swedes themselves use the thermometer of Réaumur. A prophet has no honour in his own place.

The celebrated Tar is made in these parts from the wood of different kinds of pine: chiefly from *Pinus sylvestris* and *P. Ledebourii*.

The houses being constructed of wood, the trunks are reserved for that purpose; the roots and inferior portions being used for the tar manufacture. The process is as follows:—

As far as possible they select a barren spot on the mountain side and hollow out, funnel-wise, a big conical hole destined to receive the liquid product. Then just above this huge recipient they carefully pile up the roots and waste pine wood in a mound of about 25,000 cubic metres.

They cover this gigantic mass with a thick layer of turf and moss heaped up with heavy logs, and a few holes are left to let in air.

The fire is lighted from the top: the wood burns slowly, without flame, like forest charcoal kilns, and thus furnishes a large quantity of tar without detriment to the charcoal. This tar, following the slope of the mountain, accumulates in the reservoir, from which it is made to pass, by tubes arranged for the purpose, into iron tanks, or even into hollow trunks of trees. The operation lasts from one to five weeks, according to the way the roots, etc., have been prepared.

It is clear that those who are entitled to practise pharmacy enjoy much more consideration in those countries, where they are amenable directly to a central authority, than where, as in France, they are free after gaining a diploma.

But that which in Sweden chiefly raises their status is their union in societies analogous to the French Chamber of Notaries. An unworthy member may be excluded for a time or in perpetuity by the President after a meeting of the College. The limitation of number saves them from the necessity of gaining customers by all manner of reduced prices. The public are protected by a Government tariff, with fairly remunerative prices which cannot be exceeded.

The Swedes are not subjected to governmental visitation as in France, a matter which excites the indignation of Monsieur Labonne. He considers that the granting of a diploma should be accepted as sufficient guarantee for honourable conduct. Swedish pharmacy has, however, in his opinion, one grave inconvenience—the small number of pharmacies. These are transmitted from father to son; and from uncle to nephew. A number of well-educated young men, therefore, are forced to leave their native land, and to seek in France the means of subsistence, though they they possess a title which they have laboriously acquired.

MORPHINE.*

BY O. HESSE.

The author has studied the action of acetic and propionic anhydrides on morphine and its derivatives. With regard to the nomenclature introduced by Grimaux, the author contends that the term codeïne is unjustifiable. When the hydroxylic hydrogen in morphine is replaced by the acetyl group, the resulting product is mono- (or di-) *acetylmorphine*; and when it is similarly replaced by methyl, etc., the resulting compounds should be called *methylmorphine*, etc., and not codeïne, codethyline, etc. For derivatives where one of the hydrogen-atoms of the nucleus is replaced by methyl, etc., the author proposes the name of *morphimethine*, etc.

Morphine dissolves easily in excess of acetic anhydride at 85°, to form *diacetylmorphine*. This substance crystallizes in anhydrous prisms, which are easily soluble in alcohol, sparingly so in ether, melt at 169°, and with hydrochloric acid yield a hydrochloride which gives no coloration with ferric chloride. No more highly acetylized body could be obtained. *Dipropionylmorphine* was prepared in a similar manner. It is amorphous, easily soluble in alcohol, ether, and chloroform, sparingly so in water. The *hydrochloride* is an amorphous powder easily soluble in water and yielding a pale yellow amorphous *platinochloride* $[C_{17}H_{17}(C_3H_5O)_2NO_3]_2,H_2PtCl_6$. Morphine methiodide treated with freshly precipitated silver chloride yields *morphine methochloride* crystallizing in long colourless needles, containing $2H_2O$, which it loses at 120°. It dissolves in concentrated sulphuric acid without discoloration, but the solution turns violet when heated. It gives a dark blue coloration with ferric chloride in aqueous solution. The *platinochloride* forms orange needles containing 1 mol. H_2O. Morphine methiodide dissolves with difficulty in acetic anhydride at 100°–120°, and forms the diacetyl-compound. The yield is, however, very bad, a much more satisfactory result being obtained with morphine methochloride. *Diacetylmorphine methochloride* crystallizes in concentrically grouped needles, which are easily soluble in water, and give no coloration with ferric chloride. From its solutions potassium iodide precipitates *diacetylmorphine methiodide*. The chloride yields a pale yellow *platinochloride* crystallizing in small needles containing one mol. H_2O, which they partly lose on exposure to the air, completely at 110°. The action of methyl iodide on morphine in the presence of bases has already been studied by Grimaux (*Pharm. Journ.*, [3], xii., 48.) With acetic anhydride codeïne (methylmorphine) gives *acetylcodeïne* crystallizing from ether in prisms which melt at 133°. When propionic is substituted for acetic anhydride, *propionylcodeïne* (*propionylmethylmorphine*) is formed; on evaporating its ethereal solution, this is left as a colourless film easily soluble in ether, benzene, and alcohol. It dissolves in sulphuric acid with a bluish tint, which turns dark blue on the addition of a trace of ferric chloride. When heated, both solutions turn dark green. It yields crystallizable salts with acids. The *hydrochloride* crystallizes in large colourless needles containing $2H_2O$, and soluble in water and alcohol: it gives a yellow crystalline *platinochloride*. The *acetate* crystallizes in colourless needles soluble in water. It loses a part of its acetic acid at 100°. The *hydriodide* crystallizing with one mol. H_2O, the *oxalate* with $3H_2O$; and the sulphate are all soluble in water. *Codeïne methochloride* (*methylmorphine methochloride*) is obtained from codeïne methiodide by

* From *Annalen*, ccxxii., 203–234. Reprinted from the *Journal of the Chemical Society*.

treatment with silver chloride; and crystallizes in large rhombic prisms with one mol. H_2O. It yields a yellow flocculent *platinochloride* with $3H_2O$. The *sulphate* gives colourless needles containing $4H_2O$. A solution of the last-named salt yields, with barium hydroxide, a colourless solution of *codeïne methylhydroxide*, which on evaporation over sulphuric acid, deposits crystals of *methocodeïne* (*methylmorphimethine*). The unchanged hydroxide solution precipitates hydrates from solutions of metallic salts, and rapidly absorbs carbonic anhydride from the air. Codeïne methiodide dissolves in acetic anhydride at 85°, and deposits oblong rectangular tables of *acetylcodeïne methiodide* on cooling. Thus obtained, the crystals are anhydrous; but on recrystallization from alcohol, colourless needles containing $4H_2O$ are obtained. The *platinochloride* forms a yellow crystalline precipitate. If a solution of sodium, potassium, ammonium, barium, or calcium hydroxide be added to an aqueous solution of codeïne methiodide, a colourless strongly alkaline solution is obtained which gradually becomes coloured, and deposits *methocodeïne*. The reaction is quickened by using an excess of the alkali and heating to boiling. The action of the alkalies is therefore to liberate the hydroxide from which the elements of water are subsequently eliminated,

$$C_{18}H_{21}NO_3,CH_3(OH) = C_{19}H_{23}NO_3 + H_2O.$$

For the preparation on a large scale, it is best to boil the methiodide with rather more than the molecular weight of potassium hydroxide, extract the hot solution with benzene, and shake out the latter with acetic acid. The acetic solution is then saturated with sodium chloride, and the precipitated chloride recrystallized from a small quantity of water. A concentrated aqueous solution of the chloride is then decomposed with sodium hydroxide, and the base at once extracted with ether. In a few minutes the ethereal solution deposits long colourless prisms of methocodeïne. Freshly precipitated, this substance dissolves freely in ether, but when crystallized only sparingly. It crystallizes from boiling alcohol in prisms, from boiling water in needles, in the latter case with one mol. H_2O. It melts at 118·5°, and dissolved in 97 per cent. alcohol gives $[\alpha]_o = -208{\cdot}6°$ when $p=4$ and $t=15°$. In moderately concentrated sulphuric acid, the base and its salts dissolve to a colourless solution, which gradually becomes of a purplish-violet tint, and turns olive-green when heated. The base gives a blue colour when heated with concentrated sulphuric acid. The *hydrochloride* crystallizes with $2H_2O$ in needles soluble in 10·8 parts of water at 18°. The platinochloride is of a dark green colour.

Methocodeïne dissolves in acetic anhydride at 85°, and yields *acetylmethocodeïne*. It melts at 66°, and gives a blue coloration with concentrated sulphuric acid. It is soluble in alcohol, sparingly so in water. The salts crystallize easily: the *hydrochloride* with $\frac{1}{2}H_2O$, the *platinochloride* with $4H_2O$, the nitrate with $3H_2O$, and the sulphate with $8H_2O$.

With methyl iodide, methocodeïne forms *α-methocodeïne methiodide*, crystallizing in prisms with $\frac{1}{2}H_2O$ and soluble in water. The *α-methochloride* is obtained from the methiodide by the action of silver chloride, but could not be obtained in a crystalline form. It gives a blue colour with concentrated sulphuric acid. The *α-platinochloride* is a yellow flocculent precipitate. α-codeïne methochloride dissolves in acetic anhydride forming *α-acetylcodeïne methochloride*, which crystallizes with $2\frac{1}{2}H_2O$ in long colourless silkly needles, easily soluble in alcohol and boiling water, sparingly so in cold water. It gives up 2 mols H_2O at 100°, but the remainder cannot be expelled without decomposition setting in. With concentrated sulphuric acid it gives a brownish-red coloration. The *platinochloride* forms a sparingly soluble yellow crystalline precipitate. An aqueous solution of the α-iodide becomes milky on addition of potassium or sodium hydroxide, and gradually deposits an oil which appears to be unchanged iodide. If, however, the solution be boiled with alkali, an oil is deposited on cooling, which solidifies after a time. This substance is not the original iodide, but is isomeric with it, and the author, therefore, names it *β-codeïne methiodide*. It differs from the α-iodide in crystalline form, in containing no water of crystallization, and in being less soluble in water. The *β-chloride* was not obtained in the crystalline form, and gave a purplish-violet colour with concentrated sulphuric acid. The *β-platinochloride* yields small orange needles: the sulphate is amorphous. Decomposed with barium hydroxide, the sulphate yields the alkaline *β-methocodeïne methylhydroxide*, which crystallizes in small colourless plates and flat prisms, soluble in water and alcohol. If the solution be evaporated at 30–40°, an amorphous deliquescent and highly caustic mass is left. This, however, is not a pure body. The *β-chloride* yields *β-acetyl-methocodeïne methochloride*, from which the β-iodide can be obtained by double decomposition. The *platinochloride* forms a yellow powder containing $3H_2O$.

These results confirm the presence of only two hydroxyl-groups in morphine; and the author points out that these two groups are different in character, the hydrogen of one being replaceable by either positive or negative radicals, that of the other only by the radicals of the fatty acids. Morphine methiodide is not decomposed by boiling with bases, whereas directly the hydroxylic hydrogen-atom is replaced by an alcohol radical, the stability of the methiodide is at once reduced, and in the presence of bases its decomposition and the introduction of the methyl radical into the nucleus takes place even at ordinary temperatures. The author believes the hydrogen-atom thus replaced to be one in close proximity to the hydroxyl-group which is only displaceable by acid radicals, and not, as Gerichten and Schrötter contend, one of those combined with the nitrogen-atom. He declines to accept as proved the formation of methylethylpropylamine by the decomposition of ethocodeïne methyl-hydroxide, on which Gerichten and Schrötter base their argument. On the latter supposition the author should have obtained dimethylpropylamine by the decomposition of methocodeïne methyl-hydroxide, whereas he only obtained trimethylamine. He believes the decomposition to take place according to the equation—

$$C_{18}H_{20}NO_3(CH_3),CH_3OH \ = \ N(CH_3)_3 + C_{15}H_{10}O_2 + CH_3{\cdot}OH + CH_2 + 2H_2O.$$

The ethyl compound would then give ethylene in the place of methylene, and this was observed by Gerichten and Schrötter, but ascribed by them to a secondary reaction.

The author is inclined to look upon *laudanine* as a morphine derivative containing propionyl, but in which the relative character and stability of the two hydroxyl-groups is different to what is the case in morphine. He is now continuing his researches in that direction.

OLIVE OIL AND ITS PRODUCTION.

The following particulars with regard to the production of olive oil in Tuscany have been furnished to Mr. Consul Inglis by one of the principal exporters in Leghorn:—

The olive oil produced in Tuscany from the first pressing of the fruit is intended for consumption as an article of food. Hence, great attention is paid both to the culture of the olive tree and the process of making oil.

The olive crop is subject to many vicissitudes, and is an uncertain one. It may be taken as a rule that a good crop does not occur more frequently than once in three years. A prolonged drought in summer may cause the greater part of the small fruit to fall off the trees. A warm and wet autumn will subject the fruit to the ravages of a maggot or worm, which eats its way into it. Fruit thus injured falls to the ground prematurely, and the oil made from it is of very bad quality, being nauseous in taste and somewhat thick and viscous. Frost following immediately on a fall of snow or sleet, when the trees are still wet, will irretrievably damage the fruit, causing it to shrivel up and greatly diminishing the yield of oil, while the oil itself has a dark colour, and loses its delicate flavour.

The olive tree in Tuscany generally blossoms in April. By November the fruit has attained its full size, though not full maturity, and the olive harvest generally commences then. The fruit, generally speaking, is gathered as it falls to the ground, either from ripeness or in windy weather. In some districts, however, and when the crop is short, the practice is to strip the fruit from the trees early in the season. When there is a full crop the harvest lasts many months, and may not be finished till the end of May, as the fruit does not all ripen simultaneously. Oil made early in the season has a deeper colour, and is distinguished by a fruity flavour, with a certain degree of pungency; while as the season advances it becomes lighter in colour, thinner in body, and milder and sweeter in taste. Oil made towards the close of the harvest in April or May from extremely ripe fruit is of a very pale straw colour, mild and sweet to the taste, though sometimes, if the fruit has remained too long on the trees, it may be slightly rancid. Oil very light in colour is much prized in certain countries, notably France; and hence, if it also possesses good quality, commands a higher price in the Tuscan markets.

The fruit of the olive tree varies just as much in quality as does the grape, according to the species of the tree itself, the nature of the soil, exposure, and climate of the locality where it grows. Some varieties of the olive tree largely grown, because thought to be better suited to the special conditions of some districts, yield a fruit which imparts a bitter taste to the oil made from it; such oil, even when otherwise perfect, ranks as a second rate quality. The highest quality of oil can only be obtained when the fruit is perfectly and uniformly sound, well ripened, gathered as soon as it has dropped from the trees, and crushed immediately with great attention. Should the fruit remain any time on the ground, particularly during wet weather, it deteriorates fast and gets an earthy taste; while if allowed to remain an undue length of time in the garners it heats, begins to decompose, and will yield only bad oil.

The process of making oil is as follows:—The fruit is crushed in a stone mill, generally moved by water power; the pulp is then put into bags made of fibre, and a certain number of these bags, piled one upon another, are placed in a press, most frequently worked by hand; when pressure is applied, the oil flows down into a channel by which it is conveyed to a receptacle or tank. When oil ceases to flow, tepid water is poured upon the bags to carry off oil retained by the bags. The pulp is then removed from the bags, ground again in the mill, then replaced in the bags and pressed a second time. The water used in the process of making oil must be quite pure; the mill, press, bags, and vessels sweet and clean, as the least taint would ruin the quality of the oil produced. The oil which has collected in the tank or receptacle just mentioned is removed day by day, and the water also drained off, as oil would suffer in quality if left in contact with water; the water also, which necessarily contains some oil mingled with it, is sent to a deposit outside, and at some distance from the crushing house, which is called the "Inferno," where it is allowed to accumulate, and the oil which comes to the surface is skimmed off from time to time. It is fit only for manufacturing purposes. After the second pressing the olive-pulp is not yet done with; it is beaten up with water by mechanical agitators moved by water-power, and then the whole discharged into open-air tanks adjoining the crushing-house. There the crushed olive kernels sink to the bottom, are gathered up and sold for fuel, fetching about 12 francs per 1000 kilos., while the *débris* of the pulp is skimmed off the surface of the tank and again pressed in bags, yielding a considerable quantity of inferior oil, called "Olio lavato," or washed oil, which, if freshly made, is even used for food by the poorer classes. The pulp then remaining has still a further use. It is sold for treatment in factories by the sulphide of carbon process, and by this method yields from 7 to 9 per cent. of oil; of course suitable only for manufacturing purposes. Only the first two pressings yield oil which ranks as first quality, subject of course to the condition of the fruit being unexceptionable. New oil is allowed to rest awhile in order to get rid of sediment: it is then clarified by passing through clean cotton wool, when it is fit for use.

The highest quality of olive oil for eating purposes should not only be free from the least taint in taste or smell, but possessed of a delicate appetizing flavour. When so many favourable conditions are needed as to growth, maturity and soundness of the fruit, coupled with great attention during the process of oil making, it is not to be wondered at that by no means all, or even the greater part of the oil produced in the most favoured districts of Tuscany, is of the highest quality. On the contrary, the bulk is inferior and defective. These defective oils are largely dealt in, both for home consumption and export, when price and not quality is the object.

In foreign countries there is always a market for inferior defective olive oil for cooking purposes, etc., provided the price be low. Price and not quality is the object, so much so that when olive oil is dear, cotton-seed, ground-nut and other oils are substituted, which bear the same relation to good olive oil that butterine and similar preparations do to real butter.

The very choicest qualities of pure olive oil are largely shipped from Leghorn to England along with the very lowest qualities, often also adulterated.

The oil put into Florence flasks is of the latter kind. Many years back this was not the case, but now it is a recognized fact that nothing but the lowest quality of oil is put into these flasks; oil utterly unfit for food, and so bad that it is a mystery to what use it is applied in England. Importers in England of oil in these flasks care nothing, however, about quality; cheapness is the only desideratum.

The best quality of Tuscan olive oil is imported in London in casks, bottled there, and bears the name of the importers alone on the label. There is no difficulty in procuring in England the best Tuscan oil, which nothing produced elsewhere can surpass; but consumers who wish to get, and are willingly to pay for the best article, must look to the name and reputation of the importers and the general excellence of all the articles they sell, which is the best guarantee they can have of quality.

THE RESIN INDUSTRY IN THE LANDES DEPARTMENT.*

BY A. RENARD.

The Landes department is the most important centre in France for the production of resin. This large triangular space of about fourteen thousand square metres, bounded upon one side by the ocean, and on the others by the Adour, the cultivated heights of the Lot et Garonne department, and the vineyards of Bordeaux, is an ancient bed of the sea, covered by sand of the Pliocene age. The sandy masses, which in many places are more than eighty metres thick, contain a few beds of clay; but at only a slight depth there occurs a compact layer, termed "alois," which is traversed with difficulty by the roots of trees, and which is one of the greatest obstacles to forest vegetation. In former times the rain-water, retained by this compact layer of sandstone, remained upon the soil, and transformed the surface of the Landes into a vast marsh; but since then numerous drainage ditches have been cut and convey the surplus water to the pools on the shore. In this way the surface has now

* From the *Moniteur Scientifique*, vol. xiii., p. 945.

become almost dry, the marshes have disappeared, and the inhabitants of these districts are no longer compelled to raise themselves on stilts to traverse the vast stretches of land, which formerly were impassable to ordinary pedestrians.

There is no doubt that before the middle ages the greater part of the Landes was covered with forest, at least upon the borders of the sea; but through the improvidence of the inhabitants these woods had been destroyed, and the sand had commenced its invading march from the sea coast, threatening to swallow all that it met upon its way. The first attempts which were made to reclaim the "dunes" date from the commencement of the eighteenth century; but it was Brémontier who, between 1787 and 1793, definitively solved the problem of the plantation of the Landes, he succeeding in consolidating more than 250 hectares of shifting "dunes." In the present day an immense forest of pines covers all this vast extent of territory, formerly uncultivated and marshy, and forms an impassable barrier to advance of the "dunes" from seaward.

The maritime pine is the tree chosen, to the exclusion of almost all others, by the Landais cultivators, and its reproduction is effected either from seeds or from cuttings; but the finest trees are those obtained from seeds, and this is the method generally followed. The sowing takes place naturally. Every four or five years a clearing is made by cutting down the least vigorous of the young trees so as to allow the others to develop under the most favourable conditions, and at the end of twenty-five or thirty years the trees are about one and a half or two metres apart. Those which at this stage still require to be removed are bled to death. This operation consists in making two large gashes on opposite sides of the tree, the turpentine that exudes being collected by one of the methods described subsequently. Under these conditions the tree is quickly exhausted, and at the end of four or five years is cut down. Eventually a final selection is made of the finest trees in the *pignada*, which are to be preserved for regular working, care being taken that they shall be equidistant at about eight metres; all the others are then bled to death and cut down at the end of from five to seven years. When the trees selected for preservation, which are called "*pins de place*," have attained a diameter of 30 to 35 centimetres they are ready for working.

By means of a sharp blade, slightly curved and fixed perpendicularly at the end of a wooden handle, an incision is made at the base of the tree on the side facing the east, and this is retouched every three or four months. The cutting is commenced in April and continued until the end of September, during which time it should reach a height of about half a metre. Care, however, is taken early in the season, about the beginning of March, to define the extent of the incision by removing the external surface of the bark from the part of the tree which is to be denuded. The following year the incision is continued upwards, and afterwards, for five consecutive years, until a height of two and a half or three metres is reached. A similar operation is then commenced on the side of the tree exposed towards the south, and by the time this has had its turn a return can be made to the first incision, which has become cicatrized. When the operation is well conducted a tree can be thus bled during more than two hundred consecutive years (*pendant plus de deux cents années consécutives*).

Two methods are in use to collect the exudation. The older one, which is the most simple, consists in making a small trench at the base of the tree, in which the runnings from the tree collect. While the incision is near the ground the collection is effected fairly well; but after two or three years, when the incision has attained a considerable length, the exudation reaches the ground with difficulty. Under the influence of wind and sun the greater part of the essential oil is volatilized or resinified; and the collection becomes insignificant. The second method called "Hughes's method," after its inventor, partially avoids these inconveniences, and, besides, has the advantage of yielding a "gemme" much more free from soil and vegetable *débris*. It consists in affixing to the tree, by means of a nail, a small pot, which is placed every year under the fresh cut. The turpentine thus caught, having to run a less distance to reach the recipient, is always richer in essential oil than that obtained according to the older method.

The collection of the "gemme" is made every two or three weeks. The pots are first emptied into a vessel of forty or fifty litres capacity, from which the contents are transferred to a large trench in the ground capable of holding four or five hundred litres, from which the casks are filled when required for sale. In October the resin that has solidified on the tree is gathered. This can be added to the other portion for the purpose of distillation, but usually it is kept separately, and sent into commerce under the name of "galipot" or "barasse."

The "gemme" is the primary material for the manufacture of oil of turpentine; it is a mixture, or rather a solution of colophony in the oil. Under the influence of heat the oil is volatilized and the colophony is left as a residue. The industrial distillation of the "gemme" is carried on in small factories usually situated in the midst of the forest. The season commences in the month of May and terminates in October.

On the arrival of the "gemme" at the factory it is decanted into two large wooden vats capable of containing one hundred barrels of 340 litres each. By means of a kind of saucepan fastened to the end of a long wooden staff the material is dipped from these vats and introduced into two large copper boilers, known as preparatory boilers, of six to eight barrels capacity. In these boilers the "gemme" is heated during a whole day over a low fire. The water collects at the bottom, whilst foreign substances, such as chips of wood, twigs, etc., rise to the surface, from whence they are skimmed off and put to drain in straw filters arranged above the second boiler. In the evening the fire is allowed to go down and the boiler is left to itself. In the morning the "gemme," freed in this way from the water that it held in suspension and which frequently amounts to 12 or 15 per cent., as well as earthy and ligneous matters, is introduced into a copper receiver of a fixed capacity of 300 litres. At the bottom of this pan there is a pipe, fitted with a tap, the other end of which opens at about eight inches from the bottom of the still in which the distillation has to be effected. The still is of copper and furnished with a worm that dips into a wooden receiver full of water. Three hundred litres of "gemme" are run in and heated strongly. The oil commences to distil over and at the end of fifteen or twenty minutes about eighty or a hundred litres of hot water are run into the still through a tap fixed in the upper part of it. This addition of water has for its object to facilitate the volatilization of the remainder of the essential oil. The distillate is received in a vessel made of sheet-iron and fitted at its upper part with a capacious pipe, by which the essential oil, being lighter than water, passes off into the casks set for its collction.

When the liquid issuing from the worm no longer contains much essential oil, the supply of water is stopped; the distillation is then continued for a few minutes more and the operation is finished. The yield of essential oil varies with the season and is about 15 to 18 per cent. of the weight of the "gemme." The exit pipe at the bottom of the still is then opened and the "brai," or resinous residue, is run into a sheet-iron tank, after having been made to pass over a copper plate pierced with holes, so as to eliminate various impurities that it may contain. The apparatus is then ready for a fresh operation, which is commenced without allowing it to get cold. In this way eight or ten distillations are effected daily.

After the "brai" has been allowed to cool for some time it is run into wooden casks, where it solidifies. That which is derived from "gemme" collected by Hughes's method is sent into commerce under the name of "yellow colophony" and that obtained from "gemme" collected by the old method is sold under the name of "brai clair." The resins of inferior quality, or "brais noirs," are obtained by the same method, but are the product of the distillation of the less pure portion of the "gemme" which collects towards the bottom of the preparatory boilers.

Sometimes the "brai," instead of being run directly into casks, is used for the manufacture of resin. In this case, upon issuing from the boiler of the still, it is run into a special vat, and whilst it is still liquid about 15 to 20 per cent. of hot water is added, in quantities of 20 to 30 litres at a time. The mixture is stirred energetically with staves until the whole mass has become opaque and thoroughly homogeneous; then it is run through a trough in sand into cylindrico-conical moulds also in sand, where it solidifies. The resin thus obtained is of a pale yellow shade, and under the name of "yellow resin" or "*résine de boutique*," is used in the making of resin candles.

The straw filters, upon which have been deposited all the impurities collected upon the surface of the preparatory boilers, are used for the preparation of a further quantity of "gemme" of inferior quality. They are introduced together with the detritus remaining upon them into a kiln, resembling a lime-kiln, known as a "*four à pègle*." The fire being lighted and a portion of the material burnt, determines the liquefaction of the "gemme," which runs off through an orifice situated in the lower part of the kiln into a receiver containing water. This "gemme," submitted to distillation, yields about 10 per cent. of its weight of essential oil.

Manufacture of Resin Oils.

This industry dates back half a century, and at the present time has attained a considerable development. In 1832, M. Dives, whilst distilling "gemme" for the extraction of oil of turpentine, made the observation accidentally that in continuing the operation beyond the point when only colophony was left in the still this was decomposed, giving rise to an oil. He therefore replaced the copper alembics by cast iron retorts, and the mode of distillation which he adopted is the same as is employed at the present time.

Eighteen hundred kilograms of "brai" are introduced into a large hemispherical cast iron boiler, heated over arches, together with 1½ or 2 per cent. of lime, added with the object of rendering the oils more fluid. The boiler is covered with a copper dome, which is luted with clay; this is in communication with a worm, also in copper, disposed in a vat full of cold water. Pine wood is employed as fuel in heating the boilers. The operation is commenced at three o'clock in the morning, the fire being urged strongly at the commencement, and in two or three hours the distillation begins; the fire is then moderated and maintained so until seven in the evening. The distilled products are received in a small sheet iron vessel, having in its upper part a tube by which they can be passed into the casks. At the commencement of the operation water passes over, which is run off through a tap placed in the lower part of the receiver. Afterwards about 25 kilograms of a light fraction are collected, and then nine or ten barrels of oil, each containing 160 kilograms. At the end of the operation the bottom of the boiler is brought to a dull red heat. There remains then only a solid carbonaceous residue, which has to be removed by means of a pick after each distillation.

The total yield in the lighter fraction and resin oils is about 80 to 85 per cent.; the principal loss is due to the combustible gases which are given off in abundance during the whole of the operation, and which have not hitherto been utilized.

The resin oils thus obtained are not identical throughout the entire distillation. They are distributed generally, according to their colour, into three classes: pale oils, blue oils and green oils.

The "pale oils" are the most abundant, the quantity reaching 1100 or 1200 kilograms in each operation. They are of a brownish yellow colour and rather fluid. In density they vary between 0·990 and 1·000. They are incongelable, even at very low temperatures. They possess considerable lubricating properties, but present the inconvenience of resinifying rather rapidly in contact with the air, which, together with their odour, has always limited their employment. Railway companies and miners use large quanties for lubricating machinery, after adding 25 to 50 per cent. of colza or mineral oil. They are also employed, either alone or mixed with linseed oil, in the manufacture of printing ink.

The "blue oils" consist of that portion of the products which passes over immediately after the pale oil. These oils are more coloured and have a very pronounced blue fluorescence. Their density is about ·990 to 1·000.

Lastly, when the operation approaches its termination, the "green oils" are collected, which are of a still darker shade, and possess a very strong green fluorescence. They are always mixed with a very large proportion of water, from which it is extremely difficult to free them. These oils, like the "blue oils," are more fluid than the "pale oils;" they contain, in fact, a larger proportion of a light spirit, the presence of which is due to the commencement of pyrogenation which the colophony undergoes in consequence of the high temperature to which the distillatory apparatus is submitted.

The blue and the green oils are employed especially as lubricants for waggons used in mines. As to the light spirit the proportion of which amounts to one or two per cent. of the colophony distilled, its employment is very limited. It possesses a very pronounced odour, is brownish in colour, and has a density of about 0·950. Exposed to the action of the air it resinifies rather rapidly, similarly to oil of turpentine. Occasionally it is used in the place of oil of turpentine, especially in making up paint for out-door use.

The resin oils, obtained by the method indicated, are usually sent into commerce in the same condition. They are then frequently turbid and slightly opalescent through the presence of a small quantity of water distributed through the mass. In order to render them limpid, M. Durou has proposed to allow them to stand some time in large reservoirs arranged under glass roofing, exposed to the sun. Under the influence of heat and light the oil clarifies pretty rapidly, especially in summer, and at the same time undergoes a slight decoloration. The same result is also attained by a rectification, and for this purpose the apparatus used in the distillation of the colophony is employed. The operation should be conducted slowly. A certain quantity of light spirit is first collected and set aside, after which, the oil distils perfectly clear. This distillation yields very good results; but always occasions a loss of 6 to 8 per cent. The rectified oil has a density of ·972. Several processes have been proposed for removing from resin oils their odour, which in many cases constitutes an obstacle to their employment. Washing with soda, followed by agitation with sulphuric acid, is the process which appears to yield the best results, but this method of purification has not yet received any industrial application.

When a lubricant for carriages is required the "brai" is submitted to a rapid distillation not lasting more than four hours. The oil obtained under these conditions then contains a large proportion of resin, which has been carried over mechanically; it is viscous and thick, and is known as "strong" oil. To prepare the lubricant, one part of slaked lime is suspended in two parts of thin oil from a slow distillation, and one part of the thick paste so obtained is incorporated with four or five parts of "strong" oil. The resin contained in the latter combines with the lime to form a resinate of lime. The paste is stirred well, and then while still liquid it is run into barrels or boxes, where it acquires quickly the desired consistency. These lubricants are sometimes coloured by the addition of powdered pigments.

The Pharmaceutical Journal.

SATURDAY, MAY 17, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

INDIAN PHARMACOGNOSY.

AT a time when utilitarian ideas exercise so dominating an influence as they do in the present day it may savour somewhat of the Quixotic to appear to advocate the extension of technical studies to antiquarian researches respecting drugs, since these do not, superficially at least, suggest yielding much of a *quid pro quo* in pocket or reputation. Many pharmacists are already disposed—and with good reason—to complain of the little value set by the public on qualifications obtained at the cost of hard labour and hard cash in order to enable them to serve it more efficiently. Certainly there is little in this direction to encourage the pharmaceutical student to stray beyond those bounds in the science of materia medica which enclose what is absolutely requisite in order that he may be able to pass his examinations and carry on his calling creditably. Yet there have always been a few who have interested themselves in points turning upon the history as well as the sources of drugs, and have been able to appreciate a work like 'Pharmacographia,' or a series of articles like the "Notes on Indian Drugs," from the pen of Dr. DYMOCK, which were published in this Journal a year or two since and were highly prized in many quarters, though they did not escape a somewhat irrational protest at home. It may interest some, therefore, to learn that the republication of the "Notes" by Dr. DYMOCK, systematically arranged and in a collected form, has been the occasion of the appearance of an appreciative article on Indian Pharmacognosy in the *Archiv der Pharmacie*, in which Professor FLÜCKIGER, who has himself made such important contributions to this class of literature, recalls some interesting facts in the antiquities of Indian drugs.

As late as the commencement of the sixteenth century very little comparatively was known in Europe respecting India. Although the importation of its products in the middle ages depended mainly upon the enterprise of the great commercial republics of Italy, even the most powerful of them had no direct and regular intercourse with India, and only occasional travellers from one or another of them reached the famous land. The notices of its drugs in those times were therefore few and widely separated. In the sixth century, KORMAS, a Greek merchant and traveller, saw the pepper plant growing in its South Indian home and met there also sandal wood and cloves brought from the more remote east. In the ninth century, KURDADBAH, postmaster and minister of police to the caliphs of Mesopotamia, obtained certain information respecting camphor, cubebs, galanga, and pepper. A century later mention was again made of pepper by the Persian geographer ISTACHRI, and in the twelfth century the first mention was made of cardamoms as an Indian drug by IDBISI, the Arabian geographer at the court of the Norman King ROGER, at Palermo. The earliest information respecting Ceylon cinnamon dates from the thirteenth century. The fourteenth century saw members of different religious orders making their way into the peninsula, and from them came notices of ginger, and more information upon cinnamon and the important subject of pepper. But in the first half of the fifteenth century a Venetian merchant, NICCOLO DE CONTI, spent twenty-five years in India, and in his exhaustive and striking accounts of the spices and dyeing materials of Southern India went far beyond his predecessors, and may be said to have opened up a new era.

In 1497, just as the Spaniards were invading a new world in the west, the doubling of the Cape of Good Hope by the Portuguese discoverer, VASCO DA GAMA, opened up a sea route to the East Indies, a feat which his countrymen were not slow to turn to advantage in establishing an important commerce. Amongst the officials sent over to look after the interests of Portugal was THOMAS PIRES, an apothecary, who was first appointed to the "factory" in Malacca, partially apparently in the interests of pharmacy, and afterwards was sent as an ambassador from Portugal to China. Writing from Cochin, in 1516, to King MANUEL, he enumerates the drugs indigenous in the country, as well as those imported. The information contributed by this Portuguese pharmacist, though still too scanty, was an advance on what was known before. According to him frankincense came to Cochin from Arabia, as well as from Orissa, on the east coast of India, though what this latter frankincense was exactly is not now quite certain. Opium was imported from Egypt through Aden; but it was also already produced in Cambaya, north of Bengal, and Bombay. The drug was then only "eaten" (probably smoked) by kings and lords, on account of the cost. Tamarinds, on the other hand, were so cheap, as to be looked upon as a "vergelt's Gott." PIRES also met there with aloes from Socotra, Aden, Cambaya, Valencia in Aragon and Sumatra. Among the "gomas fetidas" he enumerated sagapenum, galbanum and opopanax; but neither ammoniacum nor asafœtida. He also mentioned myrrh and liquid styrax. From the mineral kingdom, which was at that time well represented in pharmacy, PIRES met with "tincar" (tincal) from Thibet and "rubine," as well as pearls from the Red Sea, Ceylon and Southern China. About the same time, another Portuguese, ODOARDO

Barbosa, wrote an account of a journey through India, in which he quoted the prices of a series of drugs that he met with in Calicut, on the Malabar coast. But a much more valuable contribution to the history of Indian drugs was made by a third Portuguese, Garcia de Orta, who in 1534 went out as physician on board an admiral's vessel and settled down at Goa as royal physician to the hospital. There he produced his famous 'Coloquios dos Simples e Drogas,' in which Indian drugs were described with a care previously unknown, the descriptions being accompanied by a mass of other useful information. Next to that of Garcia the name most worthy of mention in connection with the history of drugs in the sixteenth century is Filippo Sassetti, who writing to a friend in his native state of Florence, probably from Cochin, discoursed right intelligently of the catechu tree (*Acacia Catechu*) and Ceylon cinnamon bark. In the next century the Dutch became powerful competitors with the Portuguese for the commerce of these regions, and wrested from them successively the famous Spice Islands, or Moluccas, and Cochin. Some knowledge of the natural products of the neighbouring countries must therefore have become a desideratum to the new masters, and it was in these circumstances that Hendrick Adriaan Rheede tot Drakenstein, the Dutch governor of the Malabar coast, ordered the compilation of the 'Hortus Indicus Malabaricus,' which was not published, however until 1703, four years after his death. In this work, which consisted of twelve folio volumes and was illustrated by seven hundred and fifty plates, many of the medicinal plants of Southern India were figured and described. Another contribution to this field of literature from Holland was Burman's 'Thesaurus Zeylanicus.' After the British rule had become definitely established in India, especially by the memorable battle of Plassey, in 1757, the ground was taken up by investigators from our own country, Dr. William Roxburgh being in the front rank. In his 'Plants of the Coast of Coromandel,' published in the years from 1795 to 1819, and his 'Flora Indica,' published between 1820 and 1832, not a few plants of pharmaceutical or technical interest were figured and satisfactorily described for the first time. In 1813 another English physician, Dr. W. Ainslie, in his 'Materia Medica of Hindostan' called attention exhaustively to the popular remedies of India, a subject which had been partially dealt with three years before by Fleming in a 'Catalogue of Indian Medicinal Plants and Drugs.' Then followed a number of valuable botanical works, in which, however, pharmacognosy had no special place; among these may be mentioned Wallich's 'Plantæ Asiaticæ Rariores,' Wight's inclusive but artistically unimportant 'Illustrations of Indian Botany' and 'Icones Plantarum Indiæ Orientalis,' and Royle's 'Illustrations of the Botany and other Branches of Natural History of the Himalayan Mountains and of the Flora of Cashmere.' In 1837 this last-mentioned author, who was a medical man in the service of the East India Company, broke fresh ground in the still imperfectly worked field of Indian medicine and published an essay on 'The Antiquity of Hindoo Medicine,' a line that has been followed in more recent years in Udo Chand Dutt's 'Materia Medica of the Hindoos.' In 1842 a new phase in the literature of Indian materia medica was initiated by the issue in Calcutta, by the order of the Government, of O'Shaughnessy's 'Bengal Dispensatory,' which was but the forerunner of the 'Pharmacopœia of India,' a work prepared under the authority of Her Majesty's Secretary of State by Dr. Waring, assisted by a Committee of native and English experts, amongst whom was the late Daniel Hanbury. We have thus followed Professor Flückiger through his *résumé*, dating from the earlier notices of separate Indian drugs to a period when they were first officially catalogued and described in a national pharmacopœia. Here we must leave him, notwithstanding that a flattering mention of the place which this Journal has taken in this field of literature might have excused our pursuing the subject a little further.

There seems to be every probability that the Annual Dinner on Tuesday next, at the Holborn Restaurant, will in every respect prove to be a success equal to any of its predecessors. At the risk, therefore, of appearing to be guilty of unnecessary repetition we would urge those members and friends who desire to be present, if they have not already obtained their tickets, to apply for them today (Saturday) to the Honorary Secretary, Mr. Richard Bremridge, as it will be absolutely necessary to close the list in time to allow proper arrangements to be made. On Wednesday evening, as probably most of our readers are aware, the Conversazione will be held in the South Kensington Museum.

* * *

We have received a copy of the Report of the Executive Committee of the Chemists and Druggists' Trade Association which will be presented at the Annual Meeting of the members, to be held at the Inns of Court Hotel, Lincoln's Inn Fields, on Tuesday next, at noon. It commences with an enumeration of three cases in which members have been successfully defended in prosecutions under the Sale of Food and Drugs Act, and four cases in which proceedings have been taken for infringements of the Pharmacy Act. It then refers to the communications of the Executive with the Council of the Pharmaceutical Society in reference to the amendment of the Pharmacy Acts, and describes the course taken in petitioning Parliament for the amendment of the Medical Bill so as to provide for the representation of pharmacists on the Pharmacopœia Committee. The other work mentioned as having been done during the year is the obtaining of the issue of an Order by the Inland Revenue authorities that officers when purchasing methylated spirit for analysis shall leave a portion of the spirit sold with the seller. It is to be regretted that the Executive has again to report a decline in the strength of the Association, whilst even of the 3340 members said to be at present on the Register only 2632 appear to have paid the annual subscription. Whether this state of affairs, which has involved a further diminution of the balance in hand, is correctly attributed in the Report to "the severe and now long continued depression in trade," is in our opinion at least doubtful. We think it is rather attributable to an apathy, similar in quality, but intensified in degree, to that which has before now laid the Pharmaceutical Society, with double the number of subscribers, under the reproach of not being representative of the whole body of chemists and druggists.

* * *

France, and, indeed, the whole scientific world, has sustained another most serious loss through the death, on Monday last, of Charles Adolphe Wurtz, the eminent chemist. Barely a month has passed since, as the representative of the Faculty of Sciences and the Faculty of Medicine of Paris, he took part in the obsequies of his illustrious master, Dumas, and now he has himself been called away. Some words which he used on that occasion seem peculiarly applicable to the circumstances of his own death. "Une belle mort : elle vous a surpris au mileu des vôtres, dans le plenitude de vos facultés." It is rather remarkable that of the four eminent men who have yet delivered the Faraday lecture, two should have died within a few weeks of each other. We hope to be able to give next week some account of the life and work of M. Wurtz, who was an Honorary Member of the Pharmaceutical Society of Great Britain.

* * *

England, too, about the same hour lost one of her ablest chemists in Dr. Robert Angus Smith, who died at Colwyn Bay, in his sixty-eighth year. Dr. Smith was born in Glasgow, where also he received his early education; but he studied chemistry under Liebig, at Giessen, and more than thirty years afterwards he bore testimony, in the dedication of his most characteristic work, 'Air and Rain,' to the admiration he still retained for his great German master. His name, as a scientific man, is most closely associated with researches upon the atmosphere and its pollution by noxious gases. Upon the passing of the first Alkali Act, in 1873, he was appointed Inspector-General under its provisions, and the annual reports issued under his superintendence have evidenced the skill and tact that he brought to bear in enforcing the new, and in many quarters much disliked law.

* * *

In a review of the drug trade of New York for the year 1883, Mr. D. C. Robbins states that among the most noteworthy facts were the large increase in the importation of quinine salts and the decrease in the importation of cinchona bark for manufacturing purposes. During the year the imports of quinine salts amounted to 1,055,764 ounces, against 794,495 ounces in the previous year; whilst the imports of bark fell from 5,010,547 pounds in 1882 to 3,639,315 pounds last year. The imports of medicinal opium appear to have remained nearly stationary; but the increase in the quantity of opium specially manufactured for smoking purposes was enormous. Hitherto this opium has been imported *viâ* San Francisco, and it has been assumed that it has been consumed principally by Chinese residents; but Mr. Robbins points out that the import of smoking opium, which, previous to 1882 had never exceeded 77,196 pounds, in that year reached 106,221 pounds, and in 1883 amounted to 298,153 pounds, whilst during the same time there has been but little increase in the Chinese population in the United States.

* * *

Some idea of the extent to which the competition of the coal-tar colours continues to affect natural pigments may be gathered from the fact that the cochineal harvest in Teneriffe, which so recently as the year 1880 was estimated to produce to the farmers £600,000, is estimated to have yielded last year only £200,000, the average price having fallen from 2*s.* to 9½*d.* per pound. There also appears to be some additional anxiety in the island in respect to the future of the cactus upon which the insects are reared, and rhea grass and the sunflower have been suggested as substitutes.

* * *

In accordance with a resolution passed at the last annual meeting of the German Pharmaceutical Association, the Council of that society has nominated a "Permanent Pharmacopœia Committee," consisting of the following twenty members:—F. A. Flückiger, B. Hirsch, G. Biltz, G. Vulpius, C. Schacht, A. Kohligk, C. Brunnengräber, C. Schneider, G. Berg, G. Wolfrum, T. Salzer, C. Finkh, —Bertkau, T. Pusch, T. Wimmel, A. Oberdörffer, C. Bernbeck, O. Maschke, B. Jassory, and T. Dugend.

* * *

The Lord Chancellor has intimated his intention of adding the name of Mr. Richard Fitzhugh, Pharmaceutical Chemist, to the Commission of the Peace for the Borough of Nottingham. Mr. Fitzhugh was for several years, and until recently, a Local Secretary of the Pharmaceutical Society and Superintendent of Written Examinations, and we doubt not that many of our readers will learn with pleasure that this honour has been conferred upon him.

* * *

The Summary in the 'Medical Students' Register' for 1883, which has just been issued, shows that the total number of medical students registered last year in the three kingdoms was 1783, being 79 less than in 1882, and a lower number than has been registered since 1878. The falling off was considerable in England and Ireland, whilst in Scotland there was an excess of registrations over those in any previous year.

* * *

We have been favoured with a copy of the "Order of Exercises," which was to have been followed at the Annual Commencement of the Massachusetts College of Pharmacy, held on the 2nd inst., and notice that one of the addresses was to be delivered by Mr. Henry Sugden Evans, a former President of the Pharmaceutical Society of Great Britain.

* * *

Among the candidates selected by the Council of the Royal Society to be recommended for election at the annual meeting are—Professor G. J. Allman, Professor J. Bayley Balfour, Mr. James Bell, Professor Walter Noel Hartley, Professor J. G. McKendrick, Dr. A. Ransome, Professor C. S. Roy, and Professor M. Watson.

Provincial Transactions.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

The last meeting of the session was held at the Owens College, on April 29. Mr. F. R. Cooper, in the chair. The minutes of the previous meeting having been read and confirmed,

A lecture with experiments was given on the "Manufacture of Coal Gas," by Messrs. A. W. Duncan, F.C.S., and F. C. J. Bird, conjointly, the latter exhibiting with the lantern a series of thirty views and diagrams.

Mr. Duncan, after briefly describing the origin and formation of coal, said that the coal is carbonized in fire-clay retorts, at a temperature of 1800° or 2000° F.; the higher the temperature the greater is the volume of the gas, but with a smaller illuminating power for the same quantity consumed; the total illuminating effect of the whole of the gas produced, however, shows a gain. The coal is carbonized for from four to six hours, when the coke is withdrawn and the retorts recharged. The retorts are continually in operation, never being allowed to cool down for a period of twelve or eighteen months, when they are worn out and require renewal. The gas next bubbles through the liquid in the hydraulic main, which acts as a seal or liquid valve, preventing the backward rush of the gas when the retorts are opened. Here tar and ammoniacal liquor deposit from the cooling gas; the ammonia exists as hydrate, sulphocyanide, hyposulphite, carbonate and sulphide. In the condensers, through which the gas is next passed, the gas is thoroughly cooled, when more tar and ammoniacal liquor is deposited. Care has to be exercised, especially in the winter time, not to cool too much, or the gas would suffer deterioration by the condensation of some of its illuminating constituents. It is necessary to prevent pressure in the retorts and overcome the resistance of the several purifying arrangements and the weight of the gasometers. For this purpose there are several fan arrangements, called exhausters, for forcing the gas in the proper direction. In the early days of gas lighting, before exhausters were used, the gas was much deteriorated by the pressure, some of the hydrocarbons being decomposed and depositing dense gas-carbon around the interior of the retorts. The gas is next thoroughly freed from ammonia, which has only partially been left in the condensers and hydraulic-main; not only is the ammonia a valuable bye-product, but if left in the gas it would corrode the copper and brass fittings of the meters, etc. For the removal of the ammonia are a great variety of apparatus termed scrubbers, washers and washer-scrubbers. The best known is the coke-scrubber, being a tower filled with coke; a spray of water is distributed over the top, which slowly percolating through the coke exposes a large moist surface to the ascending gas, and thus the ammonia is absorbed. The Livesey scrubber is a very efficient one; in this the coke is replaced by a large number of grids or trays about four inches apart, each tray is formed of deal boards about half an inch thick, with the same distance between each board. In the washers there are various arrangements by which the gas is made to bubble through water. The gas still contains some sulphur compounds and carbonic acid, and to free it from these it has to pass through rectangular boxes called purifiers. There are two modes of purification, one with hydrate of lime and the other with hydrated oxide of iron. Hydrate of lime removes carbonic acid and sulphuretted hydrogen, and the sulphide of calcium produced combines with and removes the bisulphide of carbon. Oxide of iron purification gives no objectionable smell of sulphuretted hydrogen, as does the spent lime, which latter is difficult to dispose of, except from the smaller works in agricultural districts where it can be utilized as a fertilizer. The hydrated oxide of iron, however, only combines with the sulphuretted hydrogen, allowing the carbonic acid and carbon bisulphide to pass. When all the iron has been converted into sulphide, it only needs exposure to the air to be revivified; the iron is oxidized and the sulphur deposited. The oxide is repeatedly used until it contains a large amount of sulphur, when it is sold to be converted into sulphuric acid. The purified gas only requires to pass through the meter to be registered before passing into the gasometer. In the Cooper process, lime is placed in the retorts with the coal, and in this way much of the sulphur, instead of passing into the gas and needing so much purification, is left behind in the retorts in combination with the lime. The process, however, when tried in Salford, was found to deteriorate the coke so much as to prevent its adoption. One of the most promising of recent inventions in gas lighting is that of the regenerative furnace of Siemens; a bench of these are in use at the Salford Gas Works with very satisfactory results, there being a great saving of coke. By the ordinary arrangement the retorts are not heated by the direct flame but by the heated air and products of combustion. The fire has to be kept at a much higher temperature than that to which the retorts are heated, as by the time the heated air has reached the furthest retorts it has been very much cooled down. The retorts are not uniformly heated;—whilst those nearest the fire may be overheated, those furthest away are insufficiently. In the regenerative furnace, we have first the generator where air in insufficient quantity for complete combustion is passed over ignited coke; there is thus formed highly heated carbonic oxide, with some hydrocarbons; also hydrogen and oxygen from the decomposition of steam which is allowed to pass through the ignited coke. These gases pass directly under the retorts, where they are mixed with a sufficient quantity of air for their complete combustion; this air being first highly heated by the waste heat of the furnaces. This gaseous fuel can, unlike coke, be brought just where it is required and the retorts are exposed to the direct flame. By the ordinary method, under the most favourable conditions, at least double the volume of air theoretically necessary for complete combustion has to be admitted into the furnaces, thus causing a great loss of heat. In the Siemens furnace, however, the air can be much better regulated, and the quantity required is much nearer the theoretical quantity.

After the reading of the paper a discussion took place and hearty votes of thanks were accorded the authors for their paper.

The Chairman having congratulated the Association on the successful proceedings of the past session, the meeting then terminated.

MANCHESTER PHARMACY STUDENTS' ASSOCIATION.

On Saturday afternoon, May 3 (by the kind permission of the manager, Mr. Hunter), a visit was paid by members of this Association to the Salford Corporation Gas Works, at Regent Road. The party were conducted through the works, and the process of gas-making in its various stages lucidly explained by Mr. Spencer, special attention being called to an experimental retort bench now on trial at these works, in which the retorts are heated on the regenerative system, and which is said to promise most satisfactory results. At the close of the inspection a hearty vote of thanks was passed to Messrs. Hunter and Spencer.

The monthly meeting took place on Thursday evening, May 8, in the Materia Medica Museum, Owens College (by permission of the Council). The President, Mr. A. H. Jackson, B.Sc., in the chair.

Before opening the meeting the President, in a few well-chosen sentences, expressed his sincere pleasure at seeing so many members present, at the same time remarking that the Owens College was the home of many societies which, though much smaller in numbers than they were, yet did good and useful work; he also trusted that youth and energy might do much for the Association, and wished it a long and vigorous existence which might enable it to contribute to the mutual advantage of its members, to their pharmaceutical knowledge, and to the elevation and advancement of the cause of pharmacy.

The President then called upon Mr. William Kirkby to read a paper on "An Adulteration of Quince Seed."

After describing the botanical origin, microscopical structure, etc., of the quince seed, which were illustrated by diagrams and coloured plates, the author drew attention to a sample of quince seed which had undoubtedly been exhausted of the mucilage contained in its outer coats, dried, mixed with particles of some gum (probably acacia or senegal) to give its decoction the necessary viscosity, and then offered for sale. The seeds at first sight were not very dissimilar in appearance to ordinary quince seed, but from experiments made by the writer (details of which were given) they yielded, on treatment with water, a very weak and inferior mucilage.

After the reading of the paper a discussion followed, in which the President, Messrs. Thomas, Mitchell, Breeze, Elborne, and the Secretary took part.

The second paper of the evening, on "The Aconites," was then read by Mr. William Elborne.

Dividing the aconite roots of commerce into three groups, European, Indian, and Japanese, allusion was made to the distinguishing characters of the roots obtained from the various species, and their structure and chemical composition fully entered into. Reference was especially made to the microscopical distinctions between the roots of the European species, *A. Napellus*, *A. variegatum*, and *A. paniculatum*, their transverse sections showing a totally different arrangement of the vascular bundles. The paper was well illustrated by specimens and microscopical sections.

A discussion on the subject was then carried on by the President, Messrs. Duncan, Kirkby, and Breeze.

The next meeting will be held on Thursday evening, May 22, when a paper will be read on "The Poisons Act—Is Legislation Necessary?" by Mr. A. D. Breeze.

On Saturday afternoon, May 24, a visit will be made to the Botanical Gardens, Old Trafford, when Mr. William Elborne will read a paper on "The Medicinal Plants of the Month."

LEICESTER CHEMISTS' ASSOCIATION.

A lecture was delivered at the rooms of the above Association, on Wednesday evening, by Mr. H. Pickering, on "Induced Electricity."

Mr. J. J. Edwards presided, and there was a very good attendance.

The lecturer explained the various phenomena of inductive electricity in a very able manner, illustrating the different properties by means of a powerful battery, a large Ruhmkorff's coil, and numerous other electrical instruments.

The lecture was thoroughly enjoyed by those present, and at the close a hearty vote of thanks was accorded to Mr. Pickering.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, May 1, Mr. T. S. Dymond, Vice-President, in the chair.

The minutes of the previous meeting having been read and confirmed, a paper on "Animals or Plants?" by Mr. C. Shapley, was read by the Assistant Secretary.

The author first called attention to the fact that the distinctions between animals and vegetables are not in all cases so evident as might at first sight be supposed, but that, especially in the lower forms of life, a good deal of research is often necessary to establish which division certain organisms belong to, and that even then, what is considered an animal to-day may be classed as a plant to-morrow.

The principal distinctions between plants and animals were enumerated in order, and it was shown that each in turn did not hold good in all cases, and that although all of them applied in the majority of cases, yet none was perfectly absolute. Examples were given in each case of exceptions to these rules; the composition of the cell-wall (cellulose in plants, gelatine in animals) was stated to have an exception in the case of the cloak of the lower molluscs, which contained no nitrogen; the presence of starch in some animal tissues, and of chlorophyll in stentor, hydra, etc., as well as of cholesterin in certain plants, was mentioned; certain plants (protophytes) were stated to have organs of motion similar in character and constitution to those of certain animals (protozoa); and the power possessed by certain animals, *e.g.*, fresh water sponge, of decomposing CO_2 and developing chlorophyll in the presence of light was noticed. The most trustworthy distinction was shown to be that animals derive their nourishment from organic substances which they receive into their interior, while plants live on inorganic material, absorbing it from without. This was shown to hold good in nearly all cases, the few exceptions, such as euglena having been observed in the substance of a diatom, being considered doubtful. A supposed instance of metamorphosis in the case of *Volvox Globator* was referred to, and the life history of several of the lower organisms given. The author concluded by remarking that what we now believe to be simple may not be so in reality, as not only the extreme minuteness but also the great transparency of minute forms may conceal their structure from our limited powers of vision.

The paper was followed by a discussion in which the Chairman, Secretary and Mr. Ince took part.

A vote of thanks to Mr. Shapley was moved by the Secretary, seconded by Mr. Short, and carried unanimously.

The Secretary then read the following Report on Materia Medica, by Mr. W. Elborne:—

A Note on Commercial English-prepared Cod Liver Oil.

BY WILLIAM ELBORNE,

Assistant-Lecturer on Materia Medica and Pharmacy, Owens College.

The Gadidæ or Cod tribe are a family of fishes belonging to the Malacopterygious or soft-finned order. They include among others—

Gadus Morrhua	Cod,
„ æglefinus	Haddock,
„ molva	Ling,
Merlangus vulgaris	Whiting,

and are found for the most part in the seas of cold or temperate climates; from their size and tendency to congregate in particular localities, as well as from the wholesomeness of their flesh, they are consequently of great importance to man. The livers of these fish also yield valuable oil, notably that of the common cod, *G. Morrhua*.

As is well known, the chief seats of the cod-fishery are the banks of Newfoundland and the west coast of Norway, where great care appears to be bestowed upon the selection of the livers and subsequent extraction of the oil. The livers, being taken as fresh as possible, are carefully examined, those which are poor or injured being rejected; the selected livers are then well washed and dried, and afterwards put into open barrels where the oil slowly exudes and is ladled from the surface. When filtered this forms the "natural straw-yellow coloured" oil of the first quality. The livers are next transferred to a kind of water-bath, and heated to 180° F., yielding a second quality oil of a pale colour, and, by raising the temperature, inferior oils are subsequently obtained known as the light brown and dark brown oils, the latter being used chiefly by tanners and curriers.

Owing to the great increase in price of the Newfoundland and Norwegian oils during recent years the home production of oil has experienced an unwonted stimulus; large quantities being prepared at Grimsby, Whitby, Aberdeen, and other large fishing stations in the north.

The peculiarities respecting the source and preparation of the English oil, I am informed, are as follows:—A promiscuous mass of cod, haddock, ling, and whiting livers are thrown into a large tub directly they are brought ashore, stirred up with a stick, and allowed to remain until slight decomposition has taken place, the effect of which causes the rupture of the cells containing oil, which latter then escapes and rises to the surface. The oil being removed, the livers are afterwards submitted to a steaming process similar to the Norwegian method. In physical characters, taste, and odour English-prepared cod liver oil and haddock oil are undistinguishable from the famed Newfoundland and Norwegian oils (reputed to be extracted from the livers of the *cod* only).

Owing to the similarity in chemical composition of marine animal oils in general, the difficulty attending the examination and recognition of fish oils yielded by the same genus becomes more apparent.

The following, however, is a tabulated list of some results arrived at in examining seven samples of oil in reference to their specific gravity, viscosity, and rise of temperature on admixture with sulphuric acid:—

Samples of oil.	Fresh Norwegian Cod Liver.					Fresh Cod Liver English (Grimsby) Oil.	Fresh Haddock Liver (Aberdeen).
	No. 1.	No. 2.	No. 3.	No 4.	No. 5.	No. 6.	No. 7.
Specific gravity	·927	·929	·930	·926	·926	·930	·931
Lowest temperature at which it remained perfectly clear	Fah. 20°	28°	30°	26°	24°	40°	32°
Opaque	14°	22°	26°	20°	22°	36°	26°
Solid	8°	14°	16°	18°	10°	20°	16°
Viscosity	14·1	13·8	14	15·8	15·9	13·5	12·45
Rise in temperature . . .	64°–224°	64°–232°	64°–238°	66°–218°	67°–232°	64°–238°	64°–242°

The specific gravities of the above were taken at 60° Fah., in a specific gravity bottle, and the solidifying point by use of a freezing mixture of ice and salt.

The viscosity or fluidity of the oil was determined by ascertaining the rate at which it flowed through the fine aperture of a Mohr's burette as compared with water through the same aperture, and at the same temperature (20 seconds = 1).

The rise of temperature which occurs on mixing a fixed oil with concentrated sulphuric acid (specific gravity 1·845) is a reaction which has been employed by Maumené, Fehling, and others. In this case Fehling's method was followed, 6 c.c. of oil being placed in a very small white gallipot and its temperature noted, 2 c.c. of acid was then gradually added from a burette, the mixture stirred with a delicate thermometer and its highest temperature noted. In conducting these reactions the Grimsby oil (No. 6) frothed over on addition of the acid; in Nos. 1, 2, 3, 4, 5 a brown film was left on the inside of each gallipot, and in No. 7, a black film.

In reference to this report, I regret to state that time has not permitted the extension of the above table to a similar examination of other samples of cod, haddock, ling and whiting oils, which latter I had intended preparing myself; nevertheless, in due course I hope to be able to furnish such data.

Looking at the table, however, as it stands, it is noticeable that while the specific gravity of Norwegian oil is fairly constant, there are considerable differences in the temperatures at which they become opaque and solid and that their rise in temperature increases with their specific gravity; also that the English prepared cod liver oil and haddock oil are more susceptible to turbidity on being submitted to low temperatures, probably owing to the fact that the margarine or solid fat has not been previously removed by exposure to a low temperature (a process to which I believe the Norwegian and Newfoundland oils are subjected). From a commercial point of view, haddock liver oil is considered a "cod liver oil" superior to the English prepared cod liver oil referred to in this paper.

In conclusion, I beg to thank Mr. James Hart, for much valuable service and information, also Mr. Hermann Woolley.

The report was discussed by the Chairman, Secretary, Messrs. Cullinan, McDermott, Rees and Short.

The meeting then adjourned.

SOCIETY OF ARTS.

Fermentation and Distillation.

A course of Cantor lectures on "Fermentation and Distillation" was commenced on Monday, the 12th inst., by Professor W. Noel Hartley. The lecturer at first explained the principal methods used in the conversion of the starch both of grain and potatoes into sugar. In the treatment of the former malted grain is always used, the saccharification being carried on at the temperature of 73° F., almost invariably obtained by means of steam passing into a false jacket, through which, after the conversion of the starch into sugar, cold water is passed to reduce the temperature. The formation of lactic acid during this operation, the lecturer said, was rather advantageous than otherwise, because the conversion then took place more completely; phosphoric acid also tended to produce the same result. Before operating on potatoes it is usual to ascertain the proportion of starch they contain, so as to enable an estimate to be formed of the quantity of water needed for the preparation of the mash. They are then submitted to the processes of washing, cooking and mashing. The saccharification is now frequently effected by treatment with sulphuric acid. The starch grains, after being previously separated from albuminous matter by water, are heated with sulphuric acid for five hours; lime is then added, and the whole mixture is placed in a large vat. Professor Hartley then proceeded to classify the carbohydrates in three groups: (1) the amylose or starch group, $n(C_{12}H_{20}O_{10})$, including starch, dextrin, arabin, cellulose, lichenin, glycogen, inulin, and tunicin; (2) the saccharose, or cane sugar group ($C_{12}H_{22}O_{11}$), including saccharose, lactose, maltose, synanthrose, melitose, and melizitose; and (3) the glucose, or grape sugar group ($C_6H_{12}O_6$), containing dextrose, levulose, galactose, arabinose, eucalypte, inosite, sorbite, and dambonite or bornesite. The lecturer explained the connection between these groups and their constituents by means of separate quantities of water and carbon, and showed that if the elements of a molecule of water were added to starch maltose ($C_{12}H_{22}O_{11}$) was represented, whilst the abstraction of the elements of a molecule of water resulted in erythro-dextrin, which also could again be reduced to achroo-dextrin. Professor Hartley then referred to some of the differences in starch grains: those of barley burst at 99° F., and swell until a temperature of 144° F. is reached; those of maize burst at 122° F. and swell until the same temperature is arrived at; and those of acorns do not burst until 135° F., swelling until 190° F. is reached. The lecturer then mentioned some of the soluble ferments, and remarked upon the derivation and properties of diastase, maltine, invertin, emulsin, papayin, myrosin, ptyalin, pepsin, and pancreatin. Passing from these to the glucosides, he mentioned that amygdalin ($C_{20}H_{27}NO_{11}$) could be split up into bitter almond oil, prussic acid and glucose, tannin ($C_{27}H_{22}O_{17}$) into gallic acid and glucose, salicin ($C_{13}H_{18}O_7$) into saligenin and glucose, and arbutin ($C_{12}H_{16}O_7$) into hydroquinone and glucose. Professor Hartley then remarked upon the necessity of maintaining an exact temperature during saccharifying operations, not only because too great a degree of heat destroys the diastase when malt is used, but also because whilst 80 per cent. of maltose and 19 per cent. of dextrin are obtained at a temperature of 140° F. a rise of 9° in temperature leads to a loss of 40 per cent. of maltose and a corresponding increase of dextrin. In concluding the lecture Professor Hartley said many of these results obtained were due to the work of Brown and Hiron and O'Sullivan, though he mentioned the names of many others who had contributed to them.

Cupro-Ammonium Solutions.

A paper upon "Cupro-Ammonium Solutions and their Use in Waterproofing Vegetable and Paper Tissues" was read by Dr. C. R. Alder Wright before the Chemical and Physics Section of the Society of Arts on Thursday, the 8th inst. It commenced by defining a cupro-ammonium compound as a product of the combination of ammonia with copper compounds, and stated that salts of copper usually combine with four proportions of ammonia. Cupro-tetrammonium sulphate ($Cu_2NH_3)SO_4,H_2O$ is obtainable in crystals by the admixture of a concentrated solution of copper sulphate and a solution of ammonia; the salt being separable by the addition of a very strong ammonia solution or by shaking with alcohol. Similarly other cupro-tetrammonium salts can be obtained. A closely-related compound is cupro-ammonium hydroxide, prepared by dissolving cupric hydrate or agitating metallic copper in ammonia solution in presence of air; the copper oxidizes and dissolves in the ammoniacal liquor, which assumes a blue coloration more or less deep according to the time of agitation. The instability of these compounds under the influence of heat and water, alone or conjointly, is very marked, though considerably lessened in the presence of a large excess of ammonia. The cupro-tetrammonium sulphate is decomposed by the addition of a large bulk of cold water, a basic insoluble copper sulphate being formed together with free ammonia and ammonium sulphate. The cupro-ammonium hydroxide solution is decomposed by addition of alcohol, a blue precipitate of hydrated copper oxide being thrown down, or by boiling, when anhydrous black copper oxide is formed and ammonia liberated. It is to the more stable forms obtained by dissolving copper salts or copper hydroxide in an excess of ammonia solution, that the name of "cupro-ammonium solutions" is given. These solutions have long been known to possess the property of apparently dissolving cellulose and various allied substances; paper, cotton-wool and similar materials disappear and are apparently dissolved upon digestion in these fluids. Some chemists assert that the substances are simply gelatinized and remain in the solution in a transparent form; but the reappearance of the cellulose as a flocculent precipitate upon neutralization by an acid or the addition of potassium cyanide solution points to a case of true solution. On evaporation to dryness of a cupro-ammonium solution in which cellulose has been dissolved, a more or less gummy residue is obtained, containing the cellulose intermixed with copper oxide and other salts; if, however, the cellulose be in excess, black oxide of copper is often not formed at all, but a green varnish-like mass of cellulose combined with copper, so that if the solution be evaporated on the surface of paper, calico, etc., just dipped in the solution, each filament of the fabric used employed becomes coated with the mass, and the whole welded together. This cement-like mass of cupro-cellulose, as it may be termed, being insoluble in water, communicates its water-resisting properties to the material so treated; the presence of copper also proves advantageous in protecting the substance and making it less prone to the attacks of insects or mould, even when kept under conditions favourable to the growth of animal and vegetable life of a parasitic nature. The use of a solution of cupro-ammonium hydroxide is found preferable to that of solutions containing cupro-ammonium salts, for not only is the action in cellulose more energetic for a given amount of copper and ammonium in solution, but various other advantages are gained. As fabrics treated with cupro-ammonium sulphate solutions will contain the soluble sulphate of ammonium and sometimes that of copper when dried, there is a tendency for the material to become porous if exposed to the dissolving action of water and also to cause an unsightly efflorescence under other conditions. On the contrary if cupro ammonium hydroxide solutions be used, all the ammonia present is volatilized, and may be recovered during the drying process; whereas with cupro-ammonium sulphate solution a considerable fraction of the ammonia is fixed as sulphate, and so lost. It is further observed that whereas iron precipitates the copper in solutions of ordinary copper salts, no such action takes place with cupro-ammonium hydrate solutions, so that cast or wrought iron tanks for the reception of the liquor, as well as steel rollers and machinery employed in contact with the liquor or with fabrics moistened therewith, can be used with impunity. This peculiarity is the more remarkable as this non-action is not observed with metal zinc, which precipitates the copper with about equal facility, whether the copper be in the form of an ordinary copper salt or in that of a cupro-ammonium solution. The use of copper or brass in the construction of the machinery employed must also be studiously avoided, otherwise corrosion and injury is speedily brought about. A bath containing a mixture of cupro-ammonium, and the analogous zinc-ammonium hydrate solutions, may be used with advantage for certain purposes. The zinc compound alone does not sufficiently pectise cellulose to give good results; but when used in conjunction with cupro-ammonium hydroxide, pectising is brought about by the copper solution, whilst certain advantages are obtained by the presence of the zinco-cellulose in the finished goods. As the subject of the manufacture of both cupro- and zinco-ammonium solutions has recently been dealt with in a paper read before the Society of Chemical Industry, the lecturer did not refer to it further than to state that the fluids are obtained by the simultaneous action of air and ammonia water on metallic copper (or brass, if a mixture of cupro- and zinco-ammonium hydroxides is required), due attention being paid to the recovery of the large amount of ammonia necessarily carried away by the "spent air" during the operation. The good results obtained in laboratory experiments have led to a company being formed, having their works at Willesden for the manufacture of fabrics, principally paper and canvas, treated with cupro-ammonium solutions so as to waterproof them and render them rot-proof, and practically free from the attacks of insects and moulds. Specimens have been exhibited at South Kensington in 1872 and in the Paris Exhibition of 1878, but since the latter date many improvements have been made in the nature of the plant requisite for the manufacture and the process for obtaining the essential fluid facilitated, thus enabling marketable products to be produced. These products consist of several classes and are generally known under the name of "Willesden" goods; the rope, cordage, etc., is prepared by simply dipping the made-up materials into a bath of cupro-ammonium solution, using certain precautions as to the mode of immersion and its duration, and the strength of the solution; upon drying not only is a varnish-like dressing obtained, but the fibres are strengthened by the cementing together, and many advantages are claimed as compared with similar goods protected by tarring or treated with other preservative compositions. The canvas is prepared in a somewhat similar manner, saving that the fabric to be treated is usually unwound from one roller and rewound upon another, after passing successively through the bath and a succession of drying rolls similar to those of a paper-mill. Paper is either treated in the same way as the canvas, or else a number of layers are pressed into one solid sheet of continuous lengths, whilst still pectised by the action of the cupro-ammonium solution. The uses to which these materials may be applied appear indefinite, ranging from the applications to stationery and bookbinding to the purposes of building both boats and houses. Among many illustrations shown by the lecturer to prove the superiority of fabrics treated with cupro-ammonium solutions over ordinary materials, was a specimen of paper immersed for eight consecutive weeks in a steam boiler at a pressure of 60 lbs., the only apparent change being a slight cockling at the edges. These fabrics possess many advantages over galvanized iron, both as articles of transport and for use under a tropical sun, weighing less than one-tenth a relative quantity of galvanized iron, and also allowing of being put up in compact rolls so that no space is wasted in packing; the cost of transit will therefore be less heavy. Further, being comparatively non-conducting, the heat of a tropical sun is less felt under a roof of this kind than under a metallic one, whilst no inconvenience is felt from condensation of moisture on a cold night. No change is manifest, and no unpleasant odour emitted under the hottest tropical sun, whilst no painting is required to prevent corrosion or leakage, though the surface takes paint readily if required for decorative purposes. In case of fire, although not absolutely indestructible, the "Willesdenized" materials will not readily feed the flames owing to the copperizing and compacting processes employed.

During the discussion which followed the reading of the paper many suggestions were made as to the uses to which fabrics treated with the cupro-ammonium solutions might be applied. Questions were raised as to whether the copper was an essential constituent of the fabric so treated, and also whether a plan could not be devised for submitting the materials to treatment with cupro-ammonium solutions before being made up, thus ensuring not only a superficial layer of "cupro-cellulose" but a fabric thoroughly impregnated with the solution. As to the application to electricity the fabrics were described as not ready conductors, but could not be used as safe insulators. Dr. Atcherley remarked that one of the first discoverers of the process of treating fabrics with cupro-ammonium solutions was the late Dr. John Scoffern, and also stated, as an example of the capability of these fabrics to withstand the attacks of insects, that a specimen had been placed in a white ant's nest for a period of six weeks without sustaining the slightest injury.

Parliamentary and Law Proceedings.

Poisoning by Rat Poison.

An inquest has been held at Barrow, before Mr. John Poole, on the body of Mr. T. H. Baynes, who had died from the effects of poison.

The following is the evidence relating to the sale of the poison:—

Mr. John Bryden, chemist, Old Barrow Island, said the deceased came into his shop on Monday afternoon, April 21, and asked if he had anything that would kill rats, as they were eating the ledgers in the office. Witness told him he had, and showed him several different kinds. He took one in a box, for which he paid a shilling. Witness could not say what it contained. He did not make it himself, but got it from London, and it was called "Rough on Rats." Could not say if it contained arsenic or strychnine.

The Coroner: Did you enter it in your book?

Witness: No.

The Coroner: Why?

Witness: Because I knew him so well. There is a list of poisons that we should enter, but this is not one of them.

The Coroner: You say you do not know what it contained?

Witness: Because it was not one of those mentioned in the Act.

The Coroner: But that does not exempt you under the statute from entering it, does it?

Witness said there were some rat poisons they entered in the book, even when sold to persons they knew.

The Coroner: Why did you not do it in this case?

Witness: I did not think of it at the time. The deceased was talking in his usual way, as he knew him very well. He (witness) had never opened any of these packets to see their contents. The deceased purchased the only one he had, but he had since got another packet in consequence of this case; but had not yet examined it. Witness knew the deceased well and did not notice anything wrong in his manner.

By Mr. Nalder: Had known the deceased for about nine or ten years. When he came to the shop witness was of opinion that he was on his way from dinner. He seemed to be perfectly calm, and in a happy frame of mind. Witness did not notice the slightest difference in his demeanour. They had no conversation except that relating to the sale of the rat poison. Deceased had been a customer of witness's for a long time, but never remembered having sold him rat poison before. Was sure he could not have bought any without witness knowing it. Deceased had dealt with him for about eight years, but more so since he had commenced business on Old Barrow.

By the Coroner: The deceased was not in the shop before on the same day.

Dr. Murray said on Monday evening, the 21st, he received an urgent message to proceed to the house of Mr. Baynes, West View, as his son Tom was either very ill or dying. Witness proceeded there at once, and found the deceased lying on the floor quite dead. He was partially dressed. Witness also observed some vomited matter in a basin in the bedroom, which consisted of a stringy mucus with a little blood. On Wednesday afternoon witness made a *post-mortem* examination of the body, and found it was well nourished. On examining internally he found the liver quite healthy. The lungs were also healthy but congested. The stomach contained about eight ounces of bloody fluid. The lining membrane of the stomach was intensely congested and red all over. There were no ulcerations. On the surface were particles of what appeared to be a powder. On examining the heart he found it healthy and muscular; the right side being full of blood and the left comparatively empty. Witness afterwards placed some of the powder under the microscope and found crystals of some metallic compound. From the appearance of the body immediately after death, and the vomited matters, and from the facts disclosed by the *post-mortem*, and the total absence of disease, and from what little he had heard of the case, he was forced to the conclusion that he did not die from natural causes, but from the action of some irritant poison, the mode of death being by syncope, or failure of the heart's action.

The box of rat poison mentioned by the witness Bryden was produced at this point. The witness on examining it said it was the same colour as the powder found in the stomach of the deceased.

After some further evidence the Coroner summed up, saying that there was no doubt deceased had purchased this poison with a view of taking away his life. The Act for the Sale of Poisons, 31 and 32 Vict., was passed to prevent persons getting poisons in the way this had been got. The Act was intended to meet cases of this kind, and in cases where precaution was necessary. If that precaution had been used in the present case it might perhaps never have happened. The deceased might have gone home and the strain on his mind might have passed away.

The Jury returned a verdict "That the deceased died from the effects of poison taken during a fit of temporary insanity." They also recommended that the Act with regard to the sale of poisons should be strictly enforced.—*Ulverston News.*

Obituary.

Notice has been received of the death of the following:—

On the 19th of February, Mr. Joseph Raper, Chemist and Druggist, Bradford. Aged 75 years.

On the 4th of March, Mr. Henry Jones, Chemist and Druggist, Wimborne. Aged 46 years.

On the 18th of April, Mr. Henry Cheese, Pharmaceutical Chemist, Coleford. Aged 51 years.

On the 20th of April, Mr. Walter Herbert Priestley, Chemist and Druggist, Newton Abbott. Aged 29 years. Mr. Priestley was an Associate of the Pharmaceutical Society.

On the 1st of May, Mr. John Bryne, Chemist and Druggist, Cheddar. Aged 51 years.

On the 2nd of May, Mr. Frederick Baker, Chemist and Druggist, Ottery-St.-Mary. Aged 48 years.

On the 3rd of May, Mr. James Leare, Chemist and Druggist, Sunbury. Aged 81 years.

On the 7th of May, Mr. Robert Thomas Ainsworth, Chemist and Druggist, Rusholme. Aged 38 years.

On the 8th of May, Mrs. Alice Lawton, Chemist and Druggist, Dukinfield. Aged 55 years.

On the 10th of May, Mr. William Andrew, Chemist and Druggist, Bradford, near Manchester. Aged 51 years.

Reviews.

THE COLONY OF BRITISH HONDURAS: ITS RESOURCES AND PROSPECTS. By D. MORRIS, M.A. London: E. Stanford. 1883.

The author was invited by the Government to pay a short visit to the colony of Honduras in order to investigate its flora and economic resources. The result is the account, or rather the report, contained in this work; plants of purely botanical interest being for the most part omitted, but special attention being devoted to the industrial productions of British Honduras.

The name of the colony has been chiefly connected hitherto with the trade of mahogany and logwood; and the writer endeavours to show that the place offers natural facilities for more extensive commercial enterprise.

It is somewhat discouraging to find that a fair amount of capital is indispensable to the successful colonist; and as £1000 seems the lowest estimate, a new field of energy is offered rather to the experienced cultivator than to a young man seeking to advance his fortunes in an unexplored and rising country.

It appears, however, that British Honduras has a special opening not only for sugar plantations, cacao and coffee, but for the smaller industries connected with fruit and vegetables.

The most interesting plant found wild in the forests is the india rubber tree, the *Castilloa elastica*.

The original supplies of india rubber are likely at no distant date to fall short of the demand; and as this tree is most abundant throughout the colony, great hopes may be expected from its cultivation.

The mode of extraction and preparation are detailed at length; and Mr. Morris, adopting the favourable opinion of Mr. Clements Markham, considers that this Central American rubber is well worthy of attention. The authorities of Kew have procured various rubber seeds and plants, and distributed them far and wide for the purpose of establishing them under cultivation; many cannot be easily cultivated under ordinary circumstances. The castilloa tree offers all round the most advantages, as it strikes its roots far into the ground without exhausting the surface soil; it grows with wonderful rapidity, soon forming a handsome shade tree; and lastly it gives a return in rubber within eight or ten years, while most other trees do not mature for some twenty or thirty years.

Amongst the economic plants mentioned are the vanilla, indigo, arnatto and the guaco; the last known to us as a febrifuge and anthelmintic, and possessing a local reputation as a supreme antidote against serpent's bites.

The larger industries, such as the fibre-producing plants, the sugar cane and others, hardly concern the pharmacist, but the description of nutmegs, pimento, cinnamon, cardamoms and spices generally, from an economic point of view will repay perusal.

The system of cash payment, as specially visible in the fruit trade, has given an entirely new impetus to commerce. The planter was formerly in the hands of an agent; now he can choose his own market, and secure immediate returns.

Intending settlers are advised to gain practical experience from an established colonist, before venturing on their own account, and to trust to commercial undertakings, as there are no salaried appointments in British Honduras.

The book is a careful record of the commercial capabilities of the colony, founded upon personal investigation.

MEDICAL GUIDE TO THE MINERAL WATERS OF FRANCE, AND ITS WINTERING STATIONS. By A. VINTRAS M.D., Physician to the French Embassy. London: J. and A. Churchill.

The serious study of the therapeutics of mineral waters has become a distinct branch of medicine, and one quite worthy of cultivation. As an adjunct to ordinary practice these waters are invaluable. Of late years also many springs which owed their reputation either to local tradition or to some happy accident of patronage which made them fashionable have been carefully investigated. Eminent physicians have devoted themselves to this special subject; and the result has been to the undoubted advantage of patients to whom ordinary treatment offered only partial relief. As a secondary and inevitable consequence, a wonderful impetus has been given to commercial industry. Small villages, picturesque and neglected, have risen into importance; while many thousand visitors annually crowd to the more celebrated health-resorts.

This book, by Dr. Vintras, is limited to the mineral springs of France, to which it forms a general not a particular guide. There is no attempt in its pages to exalt one locality to the detriment of another; but the intention is to describe scientifically and impartially the various French springs, to explain their medicinal value, and to give full information respecting them both to the medical world and to the public.

Acknowledgment is paid at the outset to the researches of Dr. Durand-Fardel, who has done so much to elevate hydrotherapeutics to the position of a special science.

By the term mineral water is meant natural waters which are employed in therapeutics in consequence of their chemical composition or temperature. The proportion of the mineral principles which they contain cannot be taken as distinctive, since some of the most interesting are the least strongly mineralized. The extended action which they exercise upon the constitution, on the whole of the secreting system, on the capillary circulation and on the ultimate phenomenon of nutrition, separates them from other pharmaceutical remedies. A mineral water is not a medicine which can be kept at hand and used at will; and with regard to its employment, clinical study in the hospital teaches nothing, individual experience obtained by special investigation must be the only guide.

The chemical analysis of a water is to a certain extent hypothetic, for the combinations in which its constituent elements are presented are not extracted in the form of salts; and the principles by which their acids and bases are brought into connection with each other and expressed in definite proportions are not absolute. Still the slight dissidence of chemists cannot bring any serious modification to the therapeutical character of a spring. Iron is a most usual ingredient; arsenic frequently accompanies it, especially in the mountainous region of Auvergne. Lithium has been detected by spectrum analysis; the alkalies are present in variable and characteristic proportions; but soda frequently predominates, and, according to Dr. Vintras, so great is its importance that the therapeutical value of a mineral water can be almost accurately measured by the quantity of soda which it contains.

Sufficient data have been accumulated to reduce mineral waters into a system, and to arrange them according to a definite classification.

The French system consists of four main groups:—Sulphuretted, chlorinated, bicarbonated, and sulphated. There are two other groups, indeterminate, as the simple thermal and the feebly mineralized waters; and as a supplementary group, ferruginous waters.

In adopting this classification it should be observed that predominance is not decided by the mere figures furnished by chemical analysis exclusive of therapeutic value. In the sulphuretted waters, the sulphur itself exists in an inferior proportion to the other substances, yet it determines their distinctive character. The ferruginous waters contain iron always in a secondary proportion and only as a base. They cannot, therefore, be grouped amongst the waters the classification of which is due to the predominant acid which they contain; and as iron in some proportion is almost an invariable constituent, such waters are alone reckoned ferruginous where the iron exercises a distinct medicinal influence.

Taking this system as a base, Dr. Vintras proceeds to describe in rotation the best known mineral springs in France; showing in what cases they are to be recommended, and when their use would be prejudicial to the patient. The latest analysis is in each case subjoined, and the method of their application is sketched from actual investigation.

The wintering stations occupy the concluding portion of the volume, and while Nice, Pau, Mentone, Hyères, Cannes and Biarritz are fully noticed, many other less known stations are introduced to the consideration of the reader. We can hardly imagine a more useful volume as a guide to a physician anxious to relieve a patient from a long list of maladies or their consequences which do not yield to the exhibition of pharmacopœial remedies. The pharmacist may consult these pages with advantage, as he can scarcely afford to be unacquainted with a system of medication which is now decidedly in vogue. Very sensible directions are scattered through the volume, both in the way of precaution and advice.

Correspondence.

Spirit of Nitrous Ether.

Sir,—In reply to Mr. Abraham I have only to remark that in my paper I do not admit, as he states, "the fact" alluded to by him, namely, that the standard alkali *per se* decomposes the spirit during the estimation of acidity. The decomposition which I allude to is quite a different thing, and is discussed in the paper, means for limiting the error arising therefrom being also given.

119A, *George Street, Edinburgh.* PETER MACEWAN.

T. S.—(1) *Bryum cæspitium.* (2) *Funaria hygrometrica.* (3) *Mnium hornum.* (4) *Polytrichum commune.* There is no collective work on British cryptogams of more recent date than the second edition of 'English Botany.' A work on British mosses in now being issued in parts by Dr. Braithwaite, The Ferns, Clapham Rise.

A. M.—Your question is one that turns upon a legal point, and we are therefore unable to advise you concerning it. But with respect to the first title mentioned we fail to see upon what ground you expect to be able to register and thus acquire an exclusive right to it, when you are aware that it is already in use. For our opinion as to what constitutes a "patent medicine" see the *Pharmaceutical Journal* for May 10.

An Apprentice.—See a paper on "The Preparation of Syrups of the Lactophosphates" in *Pharm. Journal*, [3], vi., 881.

S. P. S.—An article on "The Preservation of Plants for Herbaria" will be found in the *Pharmaceutical Journal*, [3], vol. iv., p. 754. A beginner will find Holmes's 'Botanical Note-Book' a useful work.

G. E. R.—(1) Such a person could not legally carry on the business, except in the capacity of a trustee or executor, and then only with the assistance of a qualified pharmacist. (2) We understand that the publishers have communicated with you on this subject.

O. H. Bott, D. Davies, Kintyre, A. P. S. and *Cymro.*—We think it hardly desirable to publish your letters, as the context of the passage to which you object shows that, although it was written somewhat unguardedly, what our correspondent wished to condemn was an undue parade of the qualification.

J. T. Hall.—(1) We are unable to supply you with a formula for a preparation resembling the proprietary article mentioned. (2) It is difficult to obtain a satisfactory result without an admixture of wax or some similar substance.

J. C. Lloyd.—It might be beneficial on account of its antiseptic properties.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Stenhouse, Brown, Sawer, Watts, T. and H. Smith, Dott, Talbot, Davies, J. W. W.

THE ANNUAL DINNER.

The Annual Dinner of the Pharmaceutical Society took place on Tuesday evening at the Holborn Restaurant, Mr. Michael Carteighe, President, in the chair. About 200 members and their friends attended, and there seemed to be but one opinion as to the excellent character of the dinner, the wine, and all the arrangements. Amongst the guests were Dr. Farquharson, M.P.; Dr. Lyons, M.P.; Sir Trevor Lawrence, M.P.; Mr. Daniel Grant, M.P.; Mr. W. Mc Cullagh Torrens, M.P.; Lieut.-Colonel Cowan (Sheriff of London and Middlesex); the President of the Medical and Chirurgical Society (Dr. George Johnson); the Secretary of the Royal Society (Professor Michael Foster); the President of the Odontological Society (Mr. T. J. Smith); the President of the Medical Society (Mr. Durham); the President of the Metropolitan Branch of the British Medical Association (Dr. C. J. Hare); the Dean of the College of Preceptors (Mr. H. W. Eve); the President of the Harveian Society (Mr. G. P. Field); the President of the Chemical Society (Dr. Perkin); the President of the Chemists' Assistants' Association (Mr. C. Parkinson); Sir Frederick Abel, Professor W. Chandler Roberts, Dr. Meymott Tidy, Dr. Lush, Dr. Stevenson, Dr. Hubbard, Dr. B. W. Richardson, Mr. E. Wyndham Cottle, Dr. Dowse, Mr. William Sowerby, Mr. H. J. Chaney (Standards Department), Mr. F. C. Danvers (Indian Office), etc.

The PRESIDENT first proposed the health of the Queen, which was received in the usual loyal and enthusiastic manner.

The next toast was "The Houses of Parliament," proposed by the PRESIDENT, who remarked that its importance was such as would allow of a very long speech if other considerations did not interfere. As far as he could see the members of the Legislature were judged from a very different standpoint inside the House to that from which they were judged outside. He had had on various occasions to see them within the precincts of the House, and he found them a very agreeable set of persons, who led a life which must be more or less horrible according to circumstances; and this impression of their lot was very much what he had experienced in some of his holiday wanderings in Switzerland, and reminded him of what was once said of a distinguished member of the literary profession and also of the Alpine Club, Mr. Leslie Stephen. That gentleman was once told by the prince of Swiss guides that it seemed a very remarkable thing that so many English gentlemen should go to Switzerland, leaving their comfortable homes and beautiful pastures, not to sit still and enjoy themselves, but to climb mountains, and to *pay* for the luxury of so doing. It seemed to him that the members of the House of Commons were very much in the position of an average Swiss mountaineer. They had an enormous deal of work to do; an immense responsibility; and in these days they had to pay heavily for the privilege of bearing these burdens. He looked upon a member of the House of Commons who did his duty as being a pattern to his countrymen; and, with regard to the House of Lords, in his opinion the two Houses were inseparable, and though they were not in the habit of inviting members of the Upper House to attend their annual meeting, none the less did those who took an interest in politics recognize the importance of that assembly. A second chamber was recognized by all who had given any thought to the questions of government to be essential, and both Liberals and Conservatives were, he believed, agreed on this point. Considering the amount of work which was done in Parliament and elsewhere by the members, he thought their constituents ought to feel greatly indebted to them. Everyone who had held office in any society or corporation knew perfectly well the enormous demands it made on their time, and considering that the House of Commons in itself represented almost everything between the smallest club and the largest corporation in the world, one might well wonder that it had not found it impossible to go on with the work which lay before it. If anyone felt inclined to complain of the paucity of the work which was done, he should remember that those outside were constantly clamouring for more and more to be undertaken. In proportion as civilization and education advanced so must the labours of Parliament increase. If, therefore, they complained that the House of Commons talked much and did little it must be borne in mind that the constituencies were in great part to blame, inasmuch as their wants were immeasurably greater than they were even twenty years ago. Although in that assembly any question of party politics would be quite out of place it was important to remember that for all practical purposes they lived under what was practically a republic. They had all the advantages of a republic with none of its disadvantages, and if the House of Commons or the House of Lords did not altogether represent what such houses should be it was due rather to the increased exigences of the country than to any fault in the Houses themselves. He would couple with the toast the name of a distinguished member of the medical profession, Dr. Lyons, Member for the City of Dublin.

DR. LYONS, M.P., in responding, said he was called upon not only to reply for the House of which he had the honour to be a member, but also for the House of Lords, and he was, therefore, glad to see around him, and, no doubt, ready to make up for shortcomings on hi part, several distinguished members of the Legislature. There were an hon. baronet, who represented the medic profession, the hon. member for West Aberdeenshire, Dr. Farquaharson, and the hon. member who represented a division of the City of London; there was also a compatriot of his, who had for many years filled a distinguished position in the Legislature, who represented an important metropolitan constituency. The President had very ably depicted the labour which devolved upon them in the present day, and he felt that he was justified in saying that that labour was becoming more and more arduous every year. So much was the public business of the country increasing, and so much was it the custom of all, under all circumstances, to look to those who represented them in Parliament for assistance in dealing with almost every conceivable question which could occupy the human mind, that no one who had not gone through the labour of the House of Commons could thoroughly appreciate how thoroughly they were occupied from morning to night. To keep abreast, even in a moderate degree, with the various questions which agitated the public mind, and on which every member was expected to be at least somewhat informed, was no slight task. Then they were obliged, though with pleasure and advantage to themselves, to see a number of persons representing important public interests, and from that constant contact with persons of the highest intelligence, representing commerce, industry and all branches of science and the arts, they derived most important advantages. In this way they were kept in constant touch with the community, and thus they endeavoured to fulfil the arduous duties which were imposed upon them, and which occupied them the greater part of the day and night. It was no longer a question of a sort of dilettante attendance on what had been called one of the best clubs in Europe, which no doubt it was, but it was also the most hard worked body in Europe that could be named. In order to secure the respect of those who came to see them on matters of public interest, they were obliged to steal from the hours usually allotted to sleep the time requisite to study those questions, and he believed it might be fairly said that an increasing proportion of members of the House of Commons were prepared to devote themselves heart and soul to the great business of the State. Much was done by those whose names became familiar in the daily papers as taking part in the debates, but much more was done of an important character by those who did silent work on committees. It was always a satisfaction to those who devoted themselves to public work to find that their efforts were appreciated, and it was a great pleasure, therefore, to him to find that this toast had been so heartily received.

The PRESIDENT next proposed "The Sheriffs of London and Middlesex." It was said that the office of Sheriff was more ancient than that of the Lord Mayor of London, but be that as it might, they were all delighted to see the right eye of the Lord Mayor,—as the Sheriff had been called,—present that evening. It was impossible to propose this toast without some reference to the corporation of London. Those who had not taken an active part in municipal affairs had some difficulty in grasping the pros and cons of the proposal now before Parliament with regard to what might be called the enlargement of the municipal boundary, but it did seem to him, speaking without any feeling of partizanship, that it pointed to a process by which all the traditions of the ancient city of London might be extended to a greater London without getting rid of them altogether. Living, as he did, outside of the City, he should be very sorry to ask the Lord Mayor and Sheriffs to come and assist those who did public duty in his neighbourhood, and at the same time to sacrifice in any way the ancient glories of their office. The difficulties of the question were very great, but above all things they should desire, while seeking to make progress in local self-government not to lose sight of those glorious traditions which belonged to the City of London and which sprang from the time when freedom was almost crushed by the royal prerogative. It was an extraordinary sign of the times that the City should be considered old fashioned and obstructive, because it carried out the form of government which was strenuously insisted upon as the preservative of freedom many hundred years ago. He would couple with the toast, the name of Lieut.-Colonel Cowan, and he would add a hope that he and his successors would all be imbued with the same desire to do justice to their fellow citizens as had animated their predecessors.

Sheriff Lieut.-Colonel COWAN thanked the meeting for the very kind way in which it had received the toast so flatteringly proposed by the President. Under ordinary circumstances he should not have departed from the rule he generally observed, not to make any allusion to political questions, but one or two remarks had been made which seemed to invite comment, with regard to the ancient municipality which he had the honour to represent. The corporation of London had existed for many years, and had been the personification of that local government and self-government under which England had prospered. As to the remark made with regard to the extension of the corporation in such a way that its ancient privileges might be extended to the more distant parts of the metropolis, he would remind his hearers that the word "local" had some limitation, and that the interest which had prompted the citizens of London to take such a lively interest in the welfare and improvement of their own surroundings could not be felt if those surroundings were extended to the vast area contemplated by the present measure. Having said so much he would only add that he thanked them very cordially for the honour which had been paid to the ancient office which he had the honour humbly to fill.

The PRESIDENT next proposed "The Learned Scientific Societies." He said the members of the Pharmaceutical Society from their early training were probably as well able to judge of the work which these societies did for the benefit of mankind as any other portion of the British public, and he held that no toast was received in a company of pharmacists with more enthusiasm. That was hardly the occasion to say much about science, but he might be allowed to remark that one of the objects of the Society which he represented as President was in a humble way to promote science in its relation to pharmacy; and that being so they naturally felt they should be doing wrong if they did not pay a tribute to the excellent work which was being done by all the great scientific societies for the benefit of mankind in general. There were present members of several learned societies, and it was rather difficult to select one in particular, but as a pharmacist he naturally turned to medicine, which had sent to the Royal Society, the father of all the learned societies, a number of distinguished men. In that spirit he proposed the toast, and associated with it the name of a distinguished professor of King's College, a Fellow of the Royal Society, a practical physician, and the President of the Medical and Chirurgical Society, Dr. George Johnson.

Dr. GEORGE JOHNSON said if he had any pride in his composition he should have begun by saying that he was very proud to respond to this toast, but as he was notoriously anything but proud he would begin by saying that he regretted exceedingly that the responsibility of responding had not fallen upon somebody better able to do justice to it. He saw around him many distinguished Fellows of the Royal Society, but he had been probably selected as being President of the Medical and Chirurgical Society. The learned and scientific societies were very numerous; he had the honour to belong to the oldest of them, and had been present at the birth of some of the youngest, and they were all doing very good work, endeavouring in various ways to extend the boundaries of human knowledge, to increase that knowledge which, in the words of Bacon, might tend to the glory of the Creator of man's estate. Amongst the sciences which were being cultivated by those societies, that of chemistry had conferred upon mankind greater benefit than almost any other, and with that science most of the gentlemen present were connected. He had a great respect for the science which had lit that room by electricity instead of the abominable gas which poisoned the atmosphere, but by far the more important was the science which had given them two most beneficial agents, although their application was due to men of his own profession, viz., anæsthetics and antiseptics. These two were about the most beneficent agents which chemistry had brought to light. If it were not considered too medical he would venture to repeat what he had heard a few days since at a branch meeting of the British Medical Society at Colchester. At that meeting Mr. Thornton showed four remarkable specimens, two of them were urinary calculi, which he had removed from patients who were perfectly well after the operation,—not from the bladder, but from the kidneys, this being quite a modern operation; the third specimen was a spleen which had undergone hopeless degeneration, which had also been removed, and the patient was doing perfectly well. But the fourth specimen was still more remarkable. A young woman was found to have a tumour in the abdomen; first it was supposed to be in the colon; this was opened under the influence, of course, of anæsthetics, and the tumour was then found to be in the stomach. The stomach was then opened, and a concrete mass of hair was removed. It appeared that this person had been in the habit of swallowing the combings of her own hair, and the result was she had a solid cast of the interior of the stomach, which Mr. Thornton removed, stitched up the stomach again, and the patient perfectly recovered. He could not give a better practical illustration of what he had said, for without the use of anæsthetics such operations would be impossible, and without antiseptics the result of opening the stomach must have been fatal. Whatever happened, therefore, the name of his distinguished friend and colleague, Sir Joseph Lister, would be handed down to posterity as one of the greatest benefactors to the human race. Amongst the learned and scientific societies, the Pharmaceutical Society of Great Britain was doing as great an amount of beneficent work as any, and he would take that opportunity of expressing his thanks to the members for the very great help which on many occasions he had received from them. They knew that doctors sometimes made mistakes in writing prescriptions; sometimes, unfortunately, they left out the water, and sometimes prescribed $\frac{1}{2}$ dr. of morphia for a dose instead of $\frac{1}{2}$ dr. of the solution, and they were very much gratified by the polite way in which these mistakes were corrected without exposing their errors to the patient.

The Vice-President proposed the next toast, "The Medical Profession." He said the goal of human search, so moralists told us, was happiness; happiness was intimately associated with and dependent upon health; it was the special function of the medical man by wise sanitation to preserve that health and when it was lost to restore it. The profession of medicine was a truly noble one, if its function were considered as thus delineated and it was remembered what perennial powers a man required to win a place in the first rank—to be endowed with talent amounting almost to genius, and then to consecrate to his profession the noblest powers of mind and heart. He must give long, deliberate and anxious preparation for his professional life, and when that curriculum was finished and he came forth to enter on the duties of his career his attention could in no wise be relaxed. Whether they considered the delicate machine he had to deal with, the masterpiece of the great Creator, or considered that he had to deal with both mind and body, it must be admitted that he was called to a truly beneficent profession, and where in the wide world could this toast be more enthusiastically received than in the centre of light and leading, in the centre of this great metropolis? Within his own time there had been marvellous advances and discoveries in medicine, and it was now scarcely an exaggeration to say that there was not an organ or function of the human body which had not its specialist, and he ventured to think that not only was that a fitting place for such a toast, but that no body of men could more cordially propose it than pharmacists, for they trusted they were not presuming when they desired to be acknowledged as belonging, however humbly, to the medical profession. Sometimes the relations between pharmacy and medicine had been somewhat strained; they had had free lances amongst them; but he could honestly say that the *rôle* of the Pharmaceutical Society had been from its earliest days to discourage encroachments on the medical profession. He did not believe in a scientific frontier, or in strict lines of delimitation by Act of Parliament, but in that which was much better and nobler, the respect and confidence which honourable men should bear one for another. They desired to protect their own rights, but at the same time to repress any poaching on other men's manors, and if amongst their ranks men had sometimes claimed that which they did not possess, or if they possessed had no legal right to make use of, it was pre-eminently the function of the Pharmaceutical Society to discountenance such proceedings. He begged to couple with the toast the name of Mr. A. E. Durham, President of the Medical Society.

Mr. A. E. Durham, in responding on behalf of the medical profession, could say most truthfully and honestly that the medical profession at large, the best and largest part of it, thoroughly appreciated how much they owed to the pharmacists of this country. An after-dinner speech was no time for argumentation and discussion, but was a very good time indeed to express personal feelings, particularly after such a good dinner as they had had on the present occasion, when they naturally felt very cordial towards each other. He would not enter on any kind of discussion as to the relative position of pharmacists and doctors, but he did feel it was thoroughly right on the part of the medical profession to express their obligations to pharmacists. Something like thirty years ago, when he was going up for his examination at the University of London, he was in a little difficulty, because he knew he had to be examined about drugs and pharmaceutical preparations, and where he was studying he felt that the preparations were bad and the drugs rotten. It then occurred to him that possibly if he went to the Pharmaceutical Society's house, in Bloomsbury Square, although he was unknown and wanted introduction, he might have an opportunity of seeing what drugs and preparations ought to be like, and so he went; he was met in the most friendly manner possible, was shown everything he wanted to see, and was told he might come as often as he liked. That was his first introduction to the Pharmaceutical Society, and it was a very pleasant one, and this was the next time he had had an opportunity of meeting them. Pharmacists helped medical men in various ways, and, to a certain extent, they taught them how to set about their work. He believed in food, and he also believed in physic. In the case of food it was not only the material which had to be considered, but how it was cooked, and in the same way the making had a good deal to do with physic; what would be nauseous, unpalatable, and indigestible and useless as a drug in one way, when properly prepared and disguised became the most valuable medicine which could be taken. Over and over again it had happened to him in his practice to be told, "It is no use prescribing so-and-so, the patient cannot take it," but when the same remedy was prescribed in some other way it was taken without difficulty, and did the good which was expected. Not only so, but some of the best teaching books that he knew with regard to medicine, and the way of prescribing medicines, had been prepared by distinguished members of the Pharmaceutical Society. He might refer particularly to the most admirable hand-book to the Pharmacopœia by his late friend, Peter Squire, and also to a more recent book, published by a well-known member of the Society, Mr. Martindale, which was the most useful book with regard to medicine that medical men could possibly have on their tables. There was one medicine he often had to prescribe, however, which was not included in the Pharmacopœia, viz., *ferrum frigidum et acutum*, but even when that was required Dr. Johnson had pointed out how usefully chemical and pharmaceutical science came in to aid the surgeon accomplishing his work successfully in relieving the patient's sufferings.

Dr. Meymott Tidy said he had been entrusted with the honour of proposing the toast of the evening, and the enthusiasm with which it would be received would in no way be dependent upon the want of originality of thought or lack of eloquence of the proposer. He did not know whether he would be excused if he ventured to use a Greek word; pharmacy and pharmacist had been, to use a Shakespearian phrase, ill-assorted. The word *pharmakis*, from which the words pharmacy and pharmacist were derived, signified not only a compounder of medicines, but a poisoner and a witch. Awkward as that was there was some ground for it, for in days gone by necromancers lived on pharmacy, and conversely pharmacy lived on necromancers, and this was the reason which gave a special charm to those old stories of the Borgias and others, and made them fitting subjects for the drama and romance. It required a tremendous power to sever the tie that bound together witchery and pharmacy; that was the work of the older pharmacists, and they set themselves to that work in right good earnest. It required a tremendous force to teach the public that the modern compounder of medicine needed no stuffed crocodile to preside over his laboratory, and no incantations to give virtue to his drugs. This divorce being effected, it was necessary to bring about a new marriage, and in effecting that the Society had played no unimportant part. It was necessary, as they had dissolved the union between witchery and pharmacy, to show that there was relationship between pharmacy and science, and it was here that the Society crept in, and the professors appointed by it set themselves to work to prove it. There never was a time in the history of the world when pharmacy was exhibited as a science in the manner in which it was at the present time. It only needed honesty of purpose and determination to oppose every form of quackery in all its protean shapes and forms, to cement the union which he honestly believed no time could sever, and no age could rust. If they were to continue this relation of science and pharmacy, they must take their care that the professors and future practitioners were men learned in their science, for if they did not establish that, one of two things would happen, either that pharmacy would soon become a kind of dead letter, or the public would lose their faith in it, or it would again form an unholy alliance with witchery and incantation. For that reason the examinations had been established which were the very foundation on which the prosperity of the Society depended. The work was not yet done, the Society had passed no finality measure; what had yet to be done was, for the most part, work of detail, but delicacy of treatment was inseparable from the carrying out of details. It was not for him to suggest those details, but many of them were known to and acknowledged by the public. In carrying them out they required a clear headed leader, judicious, firm, far-seeing, but not sensational, one who could grasp the requirements of the public as well as he could climb a mountain; a man of science who was not above being a man of the world, and such a man he ventured to think they might find in a pre-eminent degree in his friend, Michael Carteighe. He, therefore, begged to proposed the "Prosperity of the Pharmaceutical Society of Great Britain," coupled with the name of the President, Michael Carteighe.

The President, on behalf of the Society, begged to thank Dr. Tidy for having expressed in such superlative terms the merits not only of the Society which he had the honour to represent, but also his own capabilities. It was impossible for him to reply in adequate language to what had been said, especially as the hour was getting late, and therefore he would simply say that he was much obliged for the manner in which the toast had been proposed and responded to, and that all the strength he could bring to bear tending to the welfare of the Pharmaceutical Society, had been at their service. He now begged to propose the last toast of the evening, viz., "The Health of their Guests." They had amongst them men distinguished in Parliament, in science, and in various ways, some whom he knew, and some whom he had not the privilege of knowing, but to all he tendered a hearty welcome and ventured to express a hope that their time had not been spent altogether unpleasantly. He would associate with the toast the names of three gentlemen, a Member of Parliament, a representative of science, and a representative of medicine, namely, Mr. Daniel Grant, M.P., Sir Frederick Abel, and Dr. B. W. Richardson.

Mr. Daniel Grant, M.P., having briefly acknowledged the compliment,

Sir Frederick Abel said it had been his privilege and pleasure to attend many of these social gatherings, but he had never spent a more delightful evening than on that occasion. He had been associated with Mr. Carteighe in many and arduous works, and the only fault he had to find with him was that he had not given him any warning that he would have to respond to this toast; that must be his excuse for not attempting to make a speech, but it was always pleasant for chemists to meet pharmacists, they were naturally united together and belonged to one body.

Dr. Richardson said the only objection he had to responding to this toast was that he had been so long intimately connected with the Society that he could hardly fancy himself a guest. He never met with pharmacists but what he felt one of themselves and quite at home. He was, however, very glad of the opportunity to thank them, not only for their hospitality that evening, but for the progress they were making as a Society, and for the great services they rendered to medical science. The old days seemed to have passed away when the general practitioner of medicine sent out his boy heavily laden with his basket of drugs to dispense from door to door what were called remedies, and the chemist had taken in a different way a place which seemed far more rational and useful. He noticed too that as days went on they linked themselves together as two professions still more closely. There was the Pharmacopœia, which came out under the combined influence of pharmacists and physicians. There was another book which came out regularly, not officially, edited by a member of his profession and a member of theirs, which really in its character was quite equal to the official Pharmacopœia. Wherever they turned now they found that in all the advances in medicine the assistance of the pharmacist was required, and medical men, therefore, were deeply indebted to pharmacists for the help they gave them in advancing medical science, in the prevention of disease, and in the lessening of mortality.

The evening was much enlivened by some clever musical sketches by Mr. Corney Grain.

The Pharmaceutical Journal.

SATURDAY, MAY 24, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL MEETING.

THE full report of the proceedings at the various meetings of chemists and druggists in the metropolis during the past week, which appears in another part of this Journal and has involved the addition of eight extra pages, renders unnecessary, and indeed precludes any lengthened description of them in these columns. It may be remarked, however, that so far as abstention from criticism may be taken as an evidence of satisfaction, the proceedings at the Annual Meeting of the Pharmaceutical Society on Wednesday may well be accepted by the outgoing Council as an indication that the members of the Society have endorsed with their approval the account of the manner in which its business had been conducted during the past year, as laid before them in the Annual Report. The course taken also supplies another refutation of the statements which have been made on more than one occasion to the effect that the Council as an executive body is not fairly representative. The meeting was moderately well attended, and the President, following the plan adopted by him last year, instead of delivering a formal address, made a running commentary upon the topics mentioned in the Report, and concluded by moving its adoption. In this way the questions which have usually given rise to more or less discussion—not unfrequently of a very desultory and unprofitable character—appeared to be all anticipated, for the motion having been seconded by the Vice-President, no person present responded to the invitation of the Chairman to raise any discussion. It was therefore put at once and was carried by acclamation within half an hour of the commencement of the meeting. The results, too, shown in the Scrutineers' report, presented at the adjourned meeting on Friday, may be regarded as a vote of confidence, since the whole of the retiring members of the Council were re-elected by a substantial majority, the number of votes given to the successful candidate lowest on the poll exceeding the number given to the unsuccessful one next below him by as many as it fell below the highest figure polled. It appears to us, however, to be matter for regret that the absence of any burning question seems to have favoured the neglect to use the voting power to even a greater degree than usual, only about one-third of the voting papers sent out having been returned. Nevertheless this also may be taken as evidence of satisfaction so far as the members of the Society are concerned. Indeed this view of the case may be pushed further, for it may be assumed that persons who voluntarily remain outside the body which so largely controls the conditions under which their calling can be followed, are not entirely without confidence in its governing capacity.

The ordinary business of the Annual Meeting having thus been disposed of, the ground was cleared for MR. GILES to bring forward the motion of which he had given notice, a duty that he performed with his habitual eloquence. The proposition that the Council should be requested to consider and report on the best means of promoting systematic research with a view especially to the initiation, examination and improvement of formulæ for the National Pharmacopœia, contained one suggestion as to the way in which this end might best be attained, and in the course of his remarks the speaker evidently showed that he would be inclined to look for the best solution of the problem in the establishment of a special laboratory, with a staff of investigators whose time should be entirely devoted to working out the many points in connection with drugs and pharmacy which are now obscure and doubtful. Assuming that pharmaceutical research is the natural foundation of a scientific pharmacopœia, and that such research is the province of pharmacy, MR. GILES argued that the Pharmaceutical Society is responsible for fulfilling this duty, since the obligation did not rest on individuals. He said he was inclined to think that while pressing the claim of pharmacists to be associated in the compilation of the Pharmacopœia, the Society had been a little disposed to overlook its own obligations, but that when these had been fulfilled in the manner he advocated, the claims of British pharmacists to be represented on the Pharmacopœia Committee would be irresistible. Admitting and emphasizing the work done by the Society in the past, in the way of organization and education, he urged that the time had come for it to take a new departure in the direction of pharmaceutical research. In the course of the discussion that followed most of the speakers expressed sympathy with the spirit of MR. GILES's motion, though it cannot be said to have received unqualified support from any one of them. MR. MARTINDALE seemed inclined to favour the establishment of fellowships, whilst MR. LUFF leaned to the offering of prizes for the best papers on given subjects. MR. SCHACHT disputed the view that a responsibility which did not lie upon individual pharmacists could be obligatory upon the multitude of individuals that formed the Society, or that the Pharmaceutical Society would under present conditions be competent to decide what were the subjects to be investigated. MR. NAYLOR thought it was equal to a confession of weakness, a losing sight of what had been already done by individual pharmacists in original research, to say that the attainment of a *locus standi* in the Pharmacopœia Committee is dependent upon the engagement of a certain number of men to do this work for pay. But the most powerful argument against the motion was that it was inopportune. This view, which was first broached by Mr. HAMPSON and then reiterated by Mr. EKIN, was subsequently put in so cogent a form by the PRESIDENT, that Mr. GILES at once responded to his request, and, with the leave of the members present, withdrew the motion, and this practically brought the meeting to an end.

With respect to what may be termed the annual festivities, it can be said that they passed off in a most satisfactory manner. More than two hundred gentlemen sat down at the Annual Dinner on Tuesday evening, and among the guests were many eminent in medical and scientific circles, the esteem in which the Society is held having been manifested by their presence as well as by the oral testimony of those who became the spokesmen in connection with the toasts. Taken altogether, we remember no previous similar occasion on which the evening went more pleasantly or the object of the gathering was more thoroughly attained. On the following evening the President, Vice-President and Council received nearly three thousand visitors at the Conversazione, which by permission was held in the South Kensington Museum.

The Medical Bill was introduced into the House of Commons on Friday the 16th inst., and read a first time. The second reading was set down for last Thursday, but it was then postponed until next Thursday week, the 5th of June.

* * *

At a meeting of the Sheffield Pharmaceutical Association, last week, Mr. Wilkinson-Newsholme called attention to an extraordinary sample of ginger, which contained a large admixture of nux vomica seeds. The seeds, like the ginger, had been washed with lime, and, although easily recognizable by a practised eye, had thus passed through two or three different hands without notice. We understand that Mr. Newsholme is endeavouring to trace the history of this parcel, and that he proposes to bring any information he may be able to obtain before the Pharmaceutical Society at an evening meeting. We would suggest also that the names of the firms by whom this article was supplied should be made known, not necessarily for publication, but for the information of the Standing Committee on Adulteration.

* * *

According to *Le Temps* considerable interest has been excited in Paris by a report that the child of a legal functionary had been poisoned by the administration of a suppository in which morphine hydrochlorate had been substituted for quinine hydrochlorate through a mistake in dispensing in a well-known Paris pharmacy. The affair is under investigation, but meanwhile a statement has been made to a correspondent of *Le Temps* by the owner of the pharmacy, which seems to demand, at least, a suspension of judgment until the inquiry is completed. The pharmacist states that on the 23rd of March, at 5 o'clock in the afternoon, a prescription was presented at his establishment ordering some suppositories, each containing ten centigrams of quinine hydrochlorate. The prescription, having been copied correctly, was handed to an assistant to dispense, and to prevent mistake, in consequence of the relatively unusual ingredient, a special instruction was given as to where the quinine hydrochlorate would be found. The preparation was, according to the custom of the house, checked by the manager and verified before being sent out. When the suppositories were delivered the child was somewhat better, and they were, therefore, not then used; but about six weeks later, the symptoms they were intended to relieve having returned, a suppository, said to have been obtained from this pharmacy, was administered. Shortly afterwards grave symptoms were manifested which were thought to be possibly referable to the suppository, and one was sent for examination to a neighbouring pharmacist, who, after a summary examination, came to the conclusion that it contained morphine. The child was, therefore, treated for morphine poisoning, and, after some hours, the danger appeared to have passed away; but about twenty hours afterwards the child again became worse and died.

* * *

The *Weekly Drug News* of New York, in referring to the process recently described by Professor Redwood for the exhaustion of cinchona bark, speaks of it with approval as a step towards the standardizing of pharmaceutical preparations and as yielding "an elegant extract which has the great advantage of bearing dilution with water without precipitation." But it points out that this desirable quality of water solubility is secured by the elimination of the "peculiar extractive, chiefly quinovin," and demurs to the assumption, in the present state of our therapeutic knowledge, that this "quinovin" has no medicinal value. Against the reference made by Professor Redwood to Mr. Howard's opinion, it quotes a passage from Professor Flückiger's recent work, 'The Cinchona Barks Pharmacognostically Considered,' to the effect that "chinovin participates in the medicinal activity of cinchona barks." Moreover, the *Weekly Drug News* thinks that "if elegance and water solubility are the objects to be attained, the alkaloids may be employed in preference to the bark."

* * *

The *Pharmaceutical Record* calls attention to some curiosities in prescribing and dispensing as having been disclosed in a "blue book" issued by the Canadian Government, apparently giving the results of an inquiry into the working of an Act under which the registration of sales of liquors containing alcohol by druggists was made obligatory, with a view of allowing such sales when the liquor was ordered by a medical practitioner for medical purposes only. A single quotation will be sufficient to show the extent to which the permission was abused. In one drug store, from May 1 to January 1, there were 3720 prescriptions dispensed that are noted in this blue book. One particular patient, judging from the prescriptions bearing his name, was sick all this time; in fact, his state seems to have been so serious that occasionally a second physician was called in and prescribed for him. The prescription on the 1st of May was for "Spiritus

Frumenti, one bottle." This was repeated on the 3rd, on the 5th and on the 9th, on which day there were two prescriptions, each to the same effect. Between the 1st of May and the 1st of January this patient seems to have had sixty-two of these prescriptions dispensed at the same drug store, including repetitions. During the whole of this time the treatment remained unchanged, and at its close the patient still "lingered." The bearing of this experience upon the position taken by the Inland Revenue authorities in this country in respect to this question will be obvious.

* * *

Already a second edition of the new French Codex has been issued, in which several errors that had been pointed out in the first edition have been corrected. Two or three tables have been omitted and the one showing the relations of foreign medicinal weights to the gram, the incorrectness of which we were the first to point out, has been entirely reconstructed on more exact data. A remark that we made with respect to the use of the colour bands to indicate the divisions of the work seems to have been much misconstrued. One French writer saw in the remark evidence of a desire to say "*quelques malices*" and now another tells us that "the edges no longer bear those clamorous colours which caused our neighbours to smile." M. Ferrand, in the *Union Pharmaceutique*, raises the question as to the position of those pharmacists who in obedience to the decree of the 13th of February promptly obtained a copy of the new Codex, some of the formulæ in which have already been seriously modified. In order to avoid a "therapeutic disorder, as dangerous as it is ridiculous," he recommends that the Minister should give instructions to the publisher to withdraw the first edition and give in exchange copies of the second.

* * *

The French Association for the Advancement of Science will hold its third Annual Meeting on the 4th to the 11th of September, inclusive, in the city of Blois, under the presidency of M. Bouquet de la Grye.

* * *

In connection with the next Annual Meeting of the German Pharmaceutical Association, which will be held in Dresden on the 2nd, 3rd, 4th and 5th of September, there is to be a Pharmaceutical Exhibition, for the display of pharmaceutical and chemical preparations, dietetic articles, utensils, apparatus, machines and printed matter. The President of the Exhibition Committee is Dr. E. Geissler, Schreibergasse, Dresden.

* * *

On Monday next, at 9 a.m., Mr. Wyndham Dunstan will commence the course of lectures on Organic Chemistry, in connection with the School of Pharmacy of the Pharmaceutical Society. A detailed Syllabus of these Lectures, supplemented by a Synoptical Table of the Principal Hydrocarbons and their Principal Derivatives, has been prepared and published as a pamphlet.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, May 29, at 8 p.m., when some "Notes on Asafœtida" will be read by Mr. R. W. C. Pierce, and a Report on Inorganic Chemistry will be made by Mr. A. J. G. Lowe.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 21, 1884.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Robbins Savage, Schacht, Symes, Williams, and Woolley.

RESTORATIONS.

Several Members, Associates, and Apprentices were restored to membership on payment of the usual fine.

The Council considered the business of the Annual Meeting and then adjourned.

FORTY-THIRD ANNUAL GENERAL MEETING.

The PRESIDENT took the chair at twelve o'clock.

The SECRETARY having read the notice convening the meeting, the Report was taken as read.

THE ANNUAL REPORT.

The Financial Statement for 1883 shows that the income of the Society for that year exceeded the expenditure by £1526 16*s.* 7*d.* The gross receipts from the subscriptions of Members, Associates, and Apprentices are rather in excess of the previous year, although the amount received from Members only is somewhat less. The examination fees produced upwards of £700 more than in 1882, but in consequence of the larger number of candidates there has been a proportionate increase in expenditure. The Journal account leaves a small balance in favour of the Society, which, however, is about £400 less than last year.

In pursuance of a resolution referred to at the last Annual Meeting, the Council has been engaged in seeking eligible investments in freehold ground rents for a portion of the Society's invested capital. Freehold ground rents at Paddington Green amounting to £5551 5*s.* 6*d.* have been purchased, on account of the General Fund, and also at Strawberry Hill, amounting to £1020 12*s.* 6*d.*, on account of the Benevolent Fund.

The number of candidates for examination during 1883 was 396 more than in the previous year. Of this increased number 270 were candidates for the Preliminary, 116 for the Minor, 8 for the Major, and 2 for the Modified. The new regulation by which more time for answering the questions is allowed to candidates in the Preliminary examination appears to work satisfactorily.

The attendance in the Library during the past year has been considerably higher than for several previous years. The number of books circulated has been practically the same during the past three years, in 1881, 3284; in 1882, 3250; in 1883, 3240. Although it does not appear that the Parcels Post has had much influence in increasing the circulation of books, the cost of carriage has been gradually diminished. Most important English and foreign works upon the sciences and arts in which pharmacists are interested are added to the Library soon after publication. The number of volumes added during 1883 was about 250.

We, the undersigned Auditors, have examined the accounts of the Pharmaceutical Society of Great Britain, as presented in the Financial Statement and Benevolent Fund Account, and find them correct. We have inspected the Deeds relating to the Freehold Ground Rents named below, and also find that there was standing to the account of the Society at the Bank of England, and in the hands of the Society's Bankers, on the 31st December, 1883, the undermentioned Stocks, viz.:—

Fund	Stock	£	s.	d.	£	s.	d.

W. HODGKINSON,
F. HARWOOD LESCHER,
S. LLOYD STACEY,
HENRY AYSCOUGH THOMPSON, } *Auditors.*

February 28*th*, 1884.

In the Museum considerable alterations have been made. The large and rapidly increasing collection of Materia Medica has been separated into two sections, the one specially adapted for study and examination by *students*, and the other comprising such specimens of the materia medica as are most conveniently grouped for purposes of *reference*. The latter have been placed in a series of handsome new cases erected for their reception around the walls of the large examination room. Further facilities for study are now offered by the addition of three tables in No. 1 Museum, by which a larger number of students than heretofore will be enabled to examine the specimens at the same time. A glass case has been placed in No. 4 Museum, devoted especially to the exhibition of new donations to the Museum, and of drugs and chemicals of recent introduction, and it is hoped that the concentration of such articles in one place will be of service to visitors.

The materia medica collection has been enriched by the addition of a valuable series of Cinchona barks from the Government plantations in Darjeeling, and donations have been received from the Planters' Association in Ceylon and others. The value of these barks for reference is much increased by the fact that they were accompanied by herbarium specimens taken from the same trees, and that many of them have been analysed by Dr. B. H. Paul, by whom also the Madras barks mentioned in last year's report have been analysed. The results of the analyses are attached to the specimens. To the collection of Japanese drugs has been added a large number of specimens received from the Royal Gardens at Kew. An extensive collection (numbering two hundred and fifty-seven specimens) of the materia medica of Brazil and the neighbouring countries, has recently been presented by Dr. Domingo Parodi, of Buenos Ayres, and a series of native remedies, from the Hudson Bay territory, by Mr. Walton Haydon.

The Evening Meetings during the Session have been well attended, and many important papers read. With a view to increase the interest in the meetings, the Curator has been in attendance for an hour before the Chair was taken to give information respecting such specimens and apparatus as may be placed on the table for exhibition.

During 1883 one hundred and twenty cases of infringement of the Pharmacy Act, 1868, were reported, in most of which the offences were discontinued upon receipt of notice from the Registrar. In some instances it was found necessary to institute proceedings, and penalties were recovered.

In the last report it was stated that a draft Bill for the amendment of the law relating to the sale of poisons, prepared at the request of the Lord President of the Council, had been submitted to the Government. In this draft your Council had inserted such amendments of the Pharmacy Acts as were considered necessary. The Bill was not introduced last session, and in reply to an inquiry recently made, the Government have intimated that in the Bill which they propose to introduce into Parliament during the present session it is intended to deal with the sale of poisons only. Under these circumstances the Council considers that the wisest course is to suspend all further action in the matter until the publication of the Government Bill.

The Medical Acts Amendment Bill, which was withdrawn last session, has been again introduced into Parliament, but the Council regrets to have to report that the important and reasonable request addressed to the promoters of the Bill, that provision should be made for the representation of pharmacists on the Pharmacopœia Committee, has not been conceded. A Committee of the Council has charge of this matter, and it is intended to make vigorous efforts to obtain the desired representation.

The Patents, Designs and Trade Marks Act, passed at the end of the last session of Parliament, contained, when first introduced, a clause relating to the use of the Royal Arms which might have been a source of much vexation to pharmacists and others if it had become law. A correspondence on the subject between the Council and the Board of Trade resulted in a satisfactory modification of the clause which was subsequently adopted by Parliament.

The recommendations of the Education and Examinations Committee which were included in the last Annual Report have continued to receive the attention of the Council, and with a view to carrying out these recommendations as far as practicable, alterations in the Bye-Laws are being prepared, and will be submitted to the Society in due course.

The Benevolent Fund has received the careful attention of the Council. Owing to the zeal and perseverance of many of the Local Secretaries and others the income of the previous year has been well maintained. There are, however, so many members of the trade who do not subscribe that it is hoped that every Local Secretary who has not yet made a *personal* appeal on behalf of the Fund will do so. The publication in a special issue of the Journal of a local list of subscriptions and donations reported last year was repeated in February of the present year.

Commodious and suitable premises for carrying on and developing the work of the Society in Scotland have been secured by the purchase of the house, No. 36, York Place, Edinburgh.

The presentation of the Hanbury Memorial Gold Medal took place in October last, the recipient being the eminent quinologist, Mr. John Eliot Howard, a Member of this Society. The Council regrets to have to record the death of Mr. Howard within a few weeks of his having received this well-earned honour.

The Society has also lost by death amongst others, Mr. William Squire, formerly an Auditor; Mr. John Henry Atherton, formerly a member of the Council; Mr. Benjamin Humpage, also formerly an Auditor. The names of Mr. Hatrick, of Paisley, Mr. John Bray, of Sheerness, Mr. Ralph Davison, of York, and Mr. Duncanson, of Stirling, who have served the Society as Local Secretaries, have also to be added to the list of our losses for the year.

The Council has the painful duty to record the death of that veteran pharmacist, Mr. Peter Squire, one of the founders and a member of the *first* Council of the Society, whose services to it were continued with unabated zeal from its foundation until the year 1870. He filled the office of President for three years, was a member of the *first* Board of Examiners, and remained one of the most active members of that Board for the long period of twenty-seven years.

The Council cannot close this Report without reference to the loss sustained by the scientific world in the deaths of M. Dumas, the eminent French Chemist, and Professor Balfour, both Honorary Members of this Society. To the latter the Board of Examiners in Scotland was indebted for botanical specimens for examination purposes whilst he was Regius Professor of Botany in the University of Edinburgh.

The PRESIDENT said his first business was to move the adoption of the Report, in doing which it would not be necessary to detain the meeting very long. The reports of all public bodies were more or less dry when there were no dividends to declare, but at the same time this Report was interesting as a record of what had been done, and also to a certain extent of what had not been done. But this Report did not by any means represent, nor could any report represent, the amount of work which the Executive of a body like that had to get through in the course of twelve months. They were naturally anxious not to say too much, and where they could not accomplish something definite they passed over the matter without reference. The first paragraph referred to the financial statement, which might on the whole be regarded as satisfactory. There was a special paragraph with regard to the Journal, a matter in which many business men in the Society took great interest, because that was the one branch of their work in which they might be said to be carrying on a business. They were proprietors and publishers of the Journal, and members sometimes criticized their business capacity in that respect. With regard to that point, the balance was less this year than last, which might be accounted for in several ways, but broadly it was due to a somewhat diminished receipt on the score of advertisements. The Council had recommended that there should be a special issue of the *Pharmaceutical Journal* made once a year, which should be sent to every registered chemist and druggist, with a view to assisting the Benevolent Fund, and al-o showing those members of the drug trade who did not belong to the Society the sort of work it was doing, its interests and its objects. Although this special number was largely supported by advertisements, it appeared that the general income in that respect for the year was rather below the average, and consequently the increased cost of that special issue and the increased expense of distribution had made the balance reach the sum of about £400. But this was not to be looked upon entirely as wasted or lost. In all cases of advertising, they must throw their bread on the waters and trust to its being returned in increased quantity in due time. If in the course of time it was found that this special issue did not produce good results it would be quite possible to discontinue it, but it was too soon yet to say that such was the case. The next paragraph referred to the investments, on which he might say that the resolution adopted last year to transfer a certain portion of the invested capital from the funds into freehold ground rents had been carried out, and the experience thus gained distinctly confirmed the views he expressed last year of the great advantage likely to result to the Society by so doing. Last year he referred to the possibility that the Three per Cents would or might be converted, and there was actually a proposition now before Parliament which was tantamount to a conversion, the consequence of which was that the value of ground rents and all securities of that kind had gone up very materially. Nevertheless he felt certain that it would be possible to invest a portion of the capital of the Society on perfectly good security, and with very advantageous results, even at the slightly increased price which all such securities would now command. The examinations showed a considerable increase financially, but it would also be noticed that there had been a considerable number of failures. Of course from a financial point of view every person who came up for an examination was considered a fresh candidate, but as a matter of fact the real number of new candidates was considerably less than the figures indicated, because some came up two, three, four, and even six times. The Library had been very much appreciated by both the town and country members during the year, and it was the duty and pleasure of the Council to make it as useful and profitable as possible to the members. The Museum was also a source of care and interest to a large portion of the Council, and under the watchful care and active search which the Curator made for new things it had become a Museum of which they might all be proud. The Evening Meetings had been, as usual, generally interesting, and had illustrated, to some extent, the desire there was in certain quarters for pharmaceutical research. There had been about the usual number of applications with regard to infringements of the Act, and the Council had done its best to make the law obeyed. Some members at times thought it would be well, in certain cases, not to give notice to offenders before commencing proceedings, but it appeared to him that that was a mistaken view, as might be shown by an incident which had lately occurred. The Council had recently had before it a letter from the Treasury giving the particulars of a case in which an appeal had been made to remit a fine imposed upon a man who had been trading illegally, and in corresponding with that Department it had been able to show that all fair means had been taken to carry out the Act, and that no man was taken unawares and brought before a judge. With reference to the Draft Bill, they all knew that the Privy Council had decided that they would themselves deal with the question of the sale of poisons, but would not at the present time entertain any proposition which involved an amendment of the pharmacy clauses of the Act. What the exact result would be they could hardly say until the Bill was printed, but when they had it before them they would have to consider very carefully how best to protect the interests of the whole body. But although the Government said they proposed to restrict their legislation to the sale of poisons, he had not much doubt that the subject of patent medicines would be dealt with, and that the Bill would contain provisions which would commend themselves to many of their members. If it were possible for the Society to support the Government on the broad question of the sale of poisons, it would be a great advantage, because there would be then a reasonable probability that they might be able by their own efforts in Parliament, through private members, to get the pharmacy clause amended, and the various details inserted which were required for the perfection of the pharmaceutical machinery, whereas, if they had to oppose the Government tooth and nail on this point, there would be much more difficulty in dealing with pharmaceutical questions hereafter. Be that as it might, however, the Council would give every attention to the Bill when it appeared, and possibly, if the Government did not see their way to making some efforts in legislation this year, the Council might consider the desirability of moving independently in the matter. The Medical Acts Amendment Bill was read a first time last week, and was down for second reading in the House of Commons on the following day, but it was not at all probable that it would be reached for several weeks, and it would be the duty of the Council to impress first upon Mr. Mundella and afterwards on the House itself, if necessary, the importance of formally recognizing the claims of pharmacists to be on the Pharmacopœia Committee. There was no doubt this was the feeling of the Society at large, aad although to some people it appeared to be merely sentiment, it was one of those sentiments which every right-minded pharmacist ought to respect, and he was quite satisfied that the majority of the medical profession were not indisposed to consider favourably the claims of pharmacists in this direction. The Trade Marks Act passed last session contained when first introduced a rather vague clause with regard to the use of the Royal Arms, and it was the duty of the Council to take steps to have it modified, and he thought it might claim a success in that direction, because the law officers of the Crown had stated since the Bill was passed, in answer to questions, that the clause as amended would not prevent the use of the arms on labels, and in the various ways in which pharmacists and others used them. One of the things which impressed the President of the Board of Trade more than anything else was a fact he was able to state at that time that something like two million bags to hold nuts were being made in Bristol with the Royal Arms upon them, and when the difficulties of dealing with cases of that sort were pointed out he at once saw the expediency of modifying the clause. The educational business of the Society was of the first importance, and, consequently, it was with some regret that the Council was not prepared at the present moment to bring forward the complete scheme which it had been working on for several years, but in view of the uncertainties which prevailed with regard to pharmaceutical legislation it was thought expedient for the moment to give this further consideration, and to present the scheme later on. The Benevolent Fund was making satisfactory progress. They had a fair number of donations, though not quite such a windfall as during the previous year. It might be as well to mention that they had received from Mr. Baigent the sum of 100 guineas, being the fourth donation from that gentleman, and a letter had also been received from Mrs. Squire, the widow of their late colleague, stating that £100 would be forwarded by his executors for the benefit of the Fund. He would also refer to the Secretary's Casual Fund to which sundry charitable members of the trade now and then contributed, and which was found of great value, as it enabled him without delay to relieve certain distressing cases which were hardly suitable to be brought before the Committee. The value of that Fund was much greater than many members imagined, and one case which had lately occurred might be referred to in illustration. A man who had been actually in the drug trade, but who lost his situation, walked to London, could not get employment, and would very soon have become an applicant for relief from the Fund; on inquiries being made he said he could find work in his native town, but that he had not the means of getting there. He was provided with shelter and food for a few days, and then sent home with a few shillings in his pocket, and he was now earning a very good living. With reference to the North British Branch, a house had been purchased for its use in Edinburgh. Those who had not visited the existing rooms in Edinburgh probably did not know how relatively small and inconvenient they were for the purposes of examination. As the important duty of examining in Edinburgh as well as in London was imposed upon the Council, it was certainly right that proper premises should be provided in which those examinations might be conducted, and it was also thought desirable to stimulate their friends in the North to join the Society in large numbers, and work in sympathy with them. In fact that seemed to the Council an excellent way of advancing pharmacy. The house was extremely cheap, and, practically, it would cost such a capital sum as would only represent £70 or £80 a year, which was about the same as they were now paying for one floor. During the past year they had lost, by death, Mr. Howard, very soon after he received the Hanbury Gold Medal, and rather a large number of past officers of the Society. Amongst them it was only fitting to specially refer to the late Peter Squire, and, though he had elsewhere expressed his feelings with regard to him, he might again say that their sympathies were with his family in the loss they had sustained. Many of them were able to rejoice at what he as one of the founders of the Society in common with others had done, and it was right that he as one of the young generation should bear his testimony to the value which ought to be attached to those services. They had also to regret the loss of two honorary members, and since the Report was printed they had also lost another, M. Wurtz. Both that gentleman and M. Dumas had delivered the Faraday lecture in London, and possibly some members of the Society might have come in contact with them; but it was certainly an honour to have had on their roll for so many years the names of those two distinguished men. They had also lost Professor Balfour, whose special services to the members of the North British Branch were greatly appreciated. He would conclude by moving that the Report now read be received, adopted and printed in the Journal of the Society's transactions.

The VICE-PRESIDENT seconded the motion, and as no one rose in response to an invitation to make any remarks upon it, it was at once put and carried unanimously.

The PRESIDENT then called on Mr. Giles to move the resolution of which he had given notice to the following effect:—

"That the Council of the Pharmaceutical Society be requested to consider and report upon the best means of promoting systematic Pharmaceutical Research. either by the institution of a Laboratory and Staff devoted to that purpose, or by such other means as may, after full investigation, appear best calculated to effect the object in view, which shall primarily be the initiation, examination and improvement of contemplated or existing formulæ of the National Pharmacopœia."

MR. GILES said he should introduce this resolution by making one or two assumptions which would shorten the remarks he would afterwards have to make. In the first place he assumed that all members of the Society were in accord with the principles upon which the Society itself was founded and that they desired to promote scientific pharmacy. In fact what was pharmacy if it was not scientific? what right would they have to call themselves the Pharmaceutical Society unless they desired to promote pharmacy which according to his reading meant scientific pharmacy? Next he assumed that all would agree in the efforts that the Council had recently been making to establish the claims of the Society to have a recognized *locus standi* in the body charged with the preparation of the National Pharmacopœia. Those two assumptions were really of necessity associated, because no pharmacist could claim to be represented on the Pharmacopœia Committee unless he also desired to promote scientific pharmacy. He would assume, therefore, that he might argue from these premises in favour of the resolution he had the honour to propose. But first of all he would say a word or two on its form and substance. He should like also to say that from circumstances over which he had no control, he had not been able to give that amount of attention and preparation to this matter which would enable him to present it in such a satisfactory, connected and coherent manner as he should have liked. As to the form of the resolution, although it did make allusion to a laboratory and staff devoted to the purpose of pharmaceutical research, it in no wise tied the hands of the Council to that or any other method of attaining the objects in view. He confessed he did not see any other way in which it could be attained, but he did not profess to have all the wisdom in the world, and possibly the Council might see some way of attaining the desired result without the institution of a laboratory. As to the substance of the resolution, on analysing it, it would be found to essentially consist of two propositions—first, that pharmaceutical research was the natural foundation of a scientific Pharmacopœia, and next, that pharmaceutical research was the province of pharmacy—*voilà tout.* Well, if that were so, it appeared to him the resolution was established beyond the power of contradiction. If pharmaceutical research were necessary to the formation of a Pharmacopœia, and it was the province of the Pharmaceutical Society to promote pharmaceutical research—that was all the resolution said, unless they were prepared to deny that the Pharmaceutical Society was responsible for fulfilling those obligations which unquestionably did not rest on any individual pharmacist. They had no right to demand of any given pharmacist that he should devote his energies to pharmaceutical research. If he did so, so much the better, and all honour to him; but the individual duty of the man was the practice of pharmacy, scientifically, honourably and well, and there was no duty incumbent on him to occupy his time for the common good in the prosecution of pharmaceutical research. He was disposed to think that in pressing the claim which the Society made on the authorities to be associated in the manufacture of the Pharmacopœia, the Society had been a little disposed to overlook its own obligations, and it was that conviction which had led him to bring forward this proposal. It was all very well when they went outside and discussed the matter to sink all questions of shortcomings, and to press their claims strongly; that he had done himself when opportunity offered; but in that room they were meeting in council amongst themselves, and it would be most profitable to scan carefully the position, to determine the weak points and to amend them, so that when the time came they might go with an unbroken front to those whom they had to satisfy and have no weak points in their armour. He took it that none but practical, scientific pharmacists were competent to prepare a Pharmacopœia which should be level with the advances of medical and pharmaceutical science throughout the world; in fact, that was pretty well admitted by those who were charged with the duty of making the Pharmacopœia. They did not attempt to conceal their own unfitness for the task imposed upon them. That was patent, because they delegated it to someone else, in violation of the principle *delegatus non potest delegare.* He thought that gave them a correct starting point and it rested with them to do all that was necessary on their side, and then the claim which pharmacists had to be represented on the Pharmacopœia Committee, in this country as they were in all others, would be absolutely irresistible. This question was undoubtedly the question of the hour. He made no reflection on the Society for any apathy in the past of which he did not believe it had been guilty. It had dealt wisely with questions as they had arisen and had done much, which had put it in the position to do more. It had evoked organization out of chaos. It had provided for and ultimately compelled the technical and scientific education of its members, it had obtained for them such an amount of legislative protection as no other analogous body enjoyed, but it had not yet reaped all the reward it was entitled to for its labours. It had not yet succeeded in enfranchising its members, for pharmacists and agricultural labourers were the only unenfranchised subjects of Her Majesty, since they had no voice in the laws by which they were bound. Pharmacists demanded that they should not be bound by a codex which they had no hand in preparing, but which they were really the only persons concerned in carrying out. The time had now arrived when it devolved on the Society through its Council to take a new departure, but immediately this was proposed it raised a chorus of feeble opposition. There was a sort of idea that what you did not do yesterday you had no right to do to-morrow, and that what had not been done formerly it was impossible to do in the future. He had no sympathy with that idea. But he had heard a whisper that the suggestion he made, although a laudable kind of thing, which might probably lead to some interesting discussion, was nevertheless quite impracticable, and that if any such laboratory as he suggested should be organized, there would be nothing for it to do. Now, what did this sort of objection mean? did it mean anything more after all than that it would cost some money? He admitted it would cost money, but he did not see the use of money except to expend it wisely. If they could gain any adequate advantage by spending money, or undertaking extra trouble, it was very desirable to enter on the course proposed although it might involve a new departure. Societies could not remain long in a state of inaction; they must either be growing and flourishing, or decaying. Whether that Society had done growing he did not know, but it certainly had not come to the decaying period. He believed it was flourishing, and as a feature of its vigour it ought to put out every year new branches, new leaves, and new vigour, and that the time had now arrived when its inflorescence should take the form which he was now indicating, namely, taking up that which did not offer itself at first to such a Society, but which came in due course afterwards, the prosecution of pharmaceutical research. Education came first; they had to learn what other people knew, but after that it was their duty to develop something new from which other people might learn. If it were necessary to say anything on the subject of what this laboratory should do, without attempting anything like an exhaustive list, he might refer to two or three subjects of investigation. For instance, under the head of drugs there were the different qualities of drugs, the source from which they were derived and the different species of plants, as, for instance, the cinchona bark, opium, aloes, and many others; the investigation of the purity of commercial drugs and chemicals with convenient tests for adulteration; and the investigation of the relative quantities of active constituents in various parts of the plant and the different periods of growth were very much needed. Under the head of preparations there were tinctures, with reference to their alcoholic strength, the modes of exhaustion in making galenical preparations; and the standardizing of galenical preparations, a new feature, which had already been suggested in the pages of the Journal and was likely to afford great scope for original investigation. Then there was the separation and estimation of alkaloids and glucosides, etc., in drugs, and their estimation in galenical preparations; the bases for ointments; new remedies, ascertaining their active principles, and the best mode of preparing them for medicinal use, and publishing provisional formulæ with a view to uniformity. They all knew that when anything new came out there was the greatest possible range of strength, and nobody going into one pharmacy after another could be sure that he would get the same thing; hence discredit was often brought on pharmacists in consequence of there not being any quasi-official formula by which they might be guided. Then it might be said *cui bono*? what advantage would the Society derive from this procedure? First of all it would promote scientific pharmacy. That was a general statement, but a very important one, and unless the Society was prepared to go back in all its teaching, that ground alone would be sufficient to justify it in taking some steps in this direction. But more than that, he took it this was the right course and the most probable course to strengthen the claims of the Society to be represented in the Pharmacopœia Committee. The present aspect of things was entirely in favour of a change. The Medical Council in seeking to frame the Pharmacopœia had gone admittedly to the most competent persons, and who were they? The professors of pharmacy and the sciences contributory thereto in their own institution. The organization of the Society had been turned to its prejudice; the engineer had been hoist with his own petard. He made no reflection on the professors; there was not a man within or without the Society who would have done differently under similar circumstances. At all events the fact remained that the Medical Council went to men who might reasonably be supposed to have had the most experience in pharmaceutical research, which was probably true; but, nevertheless, they were not practical pharmacists, and, unfortunately, although this was a compliment to them it reflected no credit on pharmacy; it did not put pharmacy in the position in which it ought to stand, but left it under the reproach that it was unfit to be the handmaiden of medicine, unfit to meet the professors of medicine on common ground in a co-ordinate capacity. That was a bitter reproach, and the sooner it was swept away the better. Who could do this except that Society? The point had not been sufficiently insisted upon,—for it was the most important point,—that there was no organization except that Society which represented pharmacy. Pharmacy could not make its voice heard except through that Society, and the duty of every pharmacist was to stand by the Society and not to go outside and raise up rival societies which could not occupy the same ground, that would never be listened to in the same way, and never could do the good for pharmacy which that Society could do, and had done, in raising pharmacists really from an untaught mob to a scientific body.

Mr. HAMPSON objected to the word "mob."

Mr. GILES said the only difference was they had not quite so much coherence as a mob. He did not use the term in any sense as a reproach; he was one of the mob himself. But still if anyone objected to the term he would withdraw it. He commended this resolution to the meeting, and hoped it would be discussed freely. He was quite sure it would be approached in the right spirit, and though no doubt they might differ in details there were no details insisted upon. This would be only an additional reason for referring it to the Council to consider the details and bring forward something on which they could ask the opinion of the members. He believed nothing so much as this could improve the position of pharmacists in the estimation of the world, tend to their being ultimately associated in a co-ordinate capacity with the medical profession in a Pharmacopœia Committee, and help to raise to its proper status the calling of a pharmaceutical chemist, so that he should be regarded, as he really was and ought to be, a member of a scientific body.

Mr. URWICK said he would second the resolution in order that it might be fairly discussed. There were many points in Mr. Giles's remarks which must commend themselves to every pharmacist. They always wanted a standard when new tinctures or preparations were produced. For want of that each one made a form of his own, and, perhaps, his neighbour made another, and the result was that prescriptions were brought back as being not quite the same as had been obtained elsewhere, there being sometimes a difference of colour, of strength, and so on. It would be very advantageous to the trade if a laboratory were established where investigations could be carried on, and some standard published to guide in the preparation of new remedies, which now frequently became the property of one particular house, to which all had to go when the thing was ordered, or, if it was worth while to make it themselves, differences of strength were the result.

Mr. Martindale moved as an amendment that the sentence beginning "which shall" at the end of the resolution be omitted. He thought if Mr. Giles would accept it in that form it would remove a difficulty which appeared to him to exist at present, because the resolution was almost an acknowledgment that practical pharmacists were not able to give any information or to support the Medical Council in the work they had undertaken. If that were omitted it would still meet the wishes of Mr. Giles, and leave the Council a little more free to act when the resolution came before it. As Mr. Giles had pointed out there was a want of original research, for, until comparatively recently, there had been little in the way of practical pharmaceutical education. During the past few months there had been some valuable papers in that direction, which would tend no doubt to strengthen the hands of the professors who were now preparing the new Pharmacopœia; but still it left pharmacists in a very invidious position as compared to that held by their brethren in other countries. They were in the position of traders and knew best how to prepare their goods to suit the market; unquestionably they could make preparations to suit physicians and surgeons who wanted to use them better than anyone could tell them, and they knew much better for the most part the character of the drugs they had to deal with. In fact, if any medical man wished to give directions how to make a preparation, he would have to come to a practical man first to learn how it was to be done, and then having got that information would be able to give it to others. That was taking information from a source and not acknowledging it. He was rather in hopes that Mr. Giles would have brought forward some suggestion for a Fellowship of the Society, which he thought might be a great service, to be tenable for three, four or five years, with a certain income attached to it to be devoted to the purposes of investigation. If one hundred and ninety-nine chemists would give £5 each, he would give another to form a fund of £1000, from which, with the aid of a similar grant from the Council, £40 or £50 a year might be derived to endow a Fellowship. If that were done it would be a means of attaching the old students to the institution for a few years, and they would be able to do good work, not only for the whole body but for themselves. It would be an honourable position, both while it was held and afterwards, and might to some extent prevent what often occurred now, their best students leaving pharmacy and going into other work, which they found paid better.

Mr. Howard Hall seconded the amendment.

Mr. Giles said if it would at all meet the sense of the meeting he would agree to strike out the latter portion of the resolution, though he preferred it as it stood.

The President said he thought it would be better to have the whole subject open for discussion, including both the original resolution and the amendment.

Mr. Long was very glad to find there was no burning question before them at the present moment and thought this proposition was an extremely good one. They had to lament their unfortunate position in having their rights entirely ignored, for neither their rights as traders nor yet as scientific men were acknowledged. It was not at all advisable to allow themselves to sink into the position of mere traders, and no ordinary commercial men, if called upon at times, as pharmacists were, to do the work they had to do, could possible do it, but for those services they got no compensation at all. He thought the founding of a laboratory, and a system of pursuing scientific investigation, would help forward, very substantially, their claims to assist in the preparation of a Pharmacopœia. Of course this would involve a certain amount of money, but they had quite enough money now, and it was no use heaping up money which would do no actual good. It was a question with him whether it would not be desirable so to extend the laboratory that chemists might go there and supply themselves with all those preparations for which they had now to go to special houses.

Mr. Whittle agreed with Mr. Giles's proposal, but thought it would be hardly worth while to spend money on research if they were to be ignored, as they were at present, on the Pharmacopœia Committee, for, in fact, they were in no better position, if so good, as twelve months ago. He hoped now the Council would speak with no uncertain sound on this matter. The Pharmacopœia belonged as much to them as to the Medical Council, but medical men had come to their back door to get assistance instead of coming to the front. He objected to their always going hat in hand asking for concessions when they ought to insist on their rights. Chemists should put some enthusiasm into the matter, and when the Medical Council saw they were determined to be represented they would give way. He was not opposed to education by any means, but what was the use of young men spending money and working up to pass different examinations when they really got no equivalent for it?

Mr. Cross (Shrewsbury) said Mr. Giles had introduced a most important question, but he feared there were many present to whom, like himself, it came rather unexpectedly, and he thought it would be very useful if they had some expression of opinion from the Council as to their views upon the matter. No doubt the Council had paid some attention to it as it was a very important thing which would interfere with the internal management of the house, and probably they had formed some opinion upon it. He did not agree with Mr. Giles that it was altogether a new departure, and should rather call it a fresh development, but he should like to hear the views of some members of the Council before any further discussion took place.

Mr. Hampson said it was very gratifying to find that in the twelve months which had elapsed since the last annual meeting Mr. Giles must have considered that the calibre of the Council had altered, or else he would not place in its hands such a very important matter. There was no question that the resolution now proposed was very important, and he would recommend the members to exercise the greatest possible caution in forming an opinion upon it. In one sense it was distinctly a new departure, because the resolution asked the Council to consider this matter, and report upon it, which would appear to show that there still lingered in his mind some want of confidence in the Council that it had not hitherto done its duty. He thought it had, and he made bold to say that the cultivation of pharmacy was quite abreast with the times, though it was not utilized to its fullest extent of development by their medical friends. He shared Mr. Giles's strong desire to develop pharmaceutical research. What intelligent man could have any other opinion? But, on the other hand, the establishment of a committee, which would really be the result of the resolution if carried, would be most inopportune at present. Let them wait until the Medical Council recognized them on the Pharmacopœia Committee. If they looked through the Journal for the last few years there was plenty of material, and there were plenty of men capable of occupying a substantial position on any committee and to carry out as much scientific pharmacy and further research as it was necessary to meet any possible demands which medical men were likely to make. He did not oppose the resolution from any spirit of antagonism, but he thought it reflected on the Society. Its real meaning was that they had not done their duty in the past. What had the Pharmaceutical Conference been working at for many years, but pharmaceutical research; had they not voted funds year after year for the purpose?—and there was even a difficulty in appropriating the money. How were they to find a number of men to carry on this work, when no demand was being made upon them. Once let their position be properly recognized and there would be plenty of men to carry on all the research which was necessary.

Mr. Naylor said he largely sympathized with the observations made by Mr. Hampson. It seemed to him not at all flattering to them as pharmacists to be told that if they desired to be represented on the Pharmacopœia Committee some day they must attain that *locus standi* by paying a certain number of men to investigate subjects directly bearing upon their own interests, and the production of a British Pharmacopœia. He regarded that as a confession of weakness, and thought it was very illogical to come there year after year and complain of their lack of social position, and what not, and at the same time to say, here we are, why are we not represented on the Pharmacopœia Committee? If this resolution were carried they would be simply showing that the great majority were totally inadequate to the carrying out of the task, and were not fit to be entrusted with it. The resolution proposed to carry out a very important object, but he could not agree with the way in which it was proposed to be done. Mr. Giles had made a comparison between pharmacists on the Continent and themselves. He was not personally acquainted with the matter, but he should like to know whether they had become recognized by paying a certain number of men to do such work, or to acquire a certain amount of knowledge, or whether it was not due to the fact that as a body they were better educated. Moreover, Mr. Giles had largely overlooked the efforts of pharmacists in the past and in the present. Was not the present Pharmacopœia indebted to the pharmacists of the past, and would not the Pharmacopœia of the future be indebted to the research and careful investigation conducted by pharmacists of the present day? There was no doubt it would, although it might not fall directly into their hands to do it. It seemed to him that if they continued their investigations and continued to show that they possessed the necessary knowledge the time was not far distant when the Medical Council would invite their co-operation in this very important task.

Mr. Schacht said he should have been very glad, if he could have done so with a free conscience, to have endorsed this project. The motive was so clearly to stimulate them in the right direction that he felt some pain in being obliged to oppose it; but it was more in form than in substance that he differed from Mr. Giles, and he hoped to show that he was perfectly reasonable and logical in approving of the general principles, but not of the mode in which he wished those principles to be urged forward. He did not charge him with having any *arrière pensée*, but still the resolution seemed something like pledging them by a side wind to a principle which had not yet been admitted. They were not yet at all pledged to the promotion of systematic pharmaceutical research, and he hardly thought that Mr. Giles had sufficiently considered the full import of those words. Systematic pharmaceutical research was a very different thing from anything the Society had ever attempted before. As he understood the words he did not mean doing that which they had been accustomed to do, promoting scientific research indirectly, which up to the present time had been the limit of their obligations. Mr. Giles said there was no obligation on any individual pharmacist to investigate difficulties, but strangely enough he seemed to think that because there was no obligation on an individual there was an obligation on a multitude of individuals forming the Society. It seemed to him that there was no more obligation on the Society than there was on an individual member, for this reason, pharmacy was an integral portion of the medical art; it was not an independent science at all, it was simply pharmacy because it was associated with medicine. Now if they, as a part of the profession of medicine, could co-operate with other portions of the medical art for the investigation of medical subjects, well and good; but it seemed to him, as Mr. Hampson had said, that they had done their share, and that any shortcomings which existed came from the medical side proper rather than from the pharmaceutical or purely scientific. If there is one thing he should rejoice to see more than another it would be some organization which should be instituted primarily from the higher domains of medicine, the object of which should be the investigation of the conditions of the application of remedies to disease. As far as he knew no such attempt had ever been made systemically. Individuals had attempted to do this, and had more or less succeeded, but where was there any medical organization which set that duty before itself? Let anything like an approach be made to them for co-operation in such an enterprise, and then would be the time to begin to think about the systematic prosecution of pharmaceutical research. Then the difficulty incidentally arose in his mind, who is to determine what should be investigated? Mr. Giles had formulated a number of things which he thought it desirable to investigate. He (Mr. Schacht) might have as many more, and everyone else would have their own ideas to which others might object. What were those opinions worth medically? Absolutely nothing. If anything were to be investigated on the responsibility of a society it must be those subjects which the scientific medical world declared to be the proper subjects of inquiry. Then the standardizing of preparations had been referred to; but what was the use of his idea of a standard? He had no right to such an idea other than to such an one as they could all form in the shape of putting so many grains of a definite chemical into a definite solution; but he could not standardize a pharmaceutical preparation, because there was not any medical authority which had determined the medical value of any one of the things he was going to standardize. Let medical authority somewhere or other declare that such and such questions wanted to be settled, and then they might undertake to settle them, but they were required by this resolution to pledge themselves to a course which would carry them beyond what had ever been attempted by other sections of the medical art, and, therefore, it seemed to him to be premature. That was the chief objection he had to the resolution. He should like to know if any other scientific society had come to such a conclusion as this. There were many ways in which chemical observation could be be effected, but he knew of no organization which said, Here is such and such an amount of money devoted to the development of science in the abstract, nor did he know how this would constitute advance with regard to the Pharmacopœia. If the Medical Council chose to elect professors engaged in that school as experts, why should not they employ the very men who would be appointed to carry out these investigations in the same way. An investigation committee might be chosen from the rank of experts; they could hardly consist of men engaged in business. But their rights were that as practical pharmacists they should be consulted, and at the present moment their claims were at least equal to those of the medical gentlemen sitting on the Committee.

Mr. Ekin regarded this proposition as being not so much premature as inopportune, and had no doubt many would have a difficulty in voting upon it on that ground. While he heartily sympathized with Mr. Giles in the suggestion that there should be a distinct effort to promote scientific research, he feared that any effort of that sort at the present time would be misunderstood. It was a pity it should be so, but there was no doubt about it. Many of the difficulties Mr. Schacht had raised were after all only difficulties of detail. There would be no difficulty in finding subjects to investigate, and if anything of the sort were ever carried out the Council would probably nominate a certain number of their own men, possibly associated with an equal number of others, who would choose the subjects. There might be a practical difficulty in finding suitable men to carry them out, and the more one thought about it the more one realized how great those practical difficulties would be. At the same time there was no reason why they should be insuperable. With reference to one point mentioned by Mr. Giles, the probability or the possibility was that almost every different drug should be treated by a different strength of spirit, instead of their all being treated with one or at most two strengths. That was a very important work which no one individual could undertake, but which might be taken up by a society. It was quite practical, and would be very useful, and would be to the credit of the Society. At the same time he felt that if this resolution were carried now, it would be very much misunderstood.

Mr. Luff cordially agreed with the assumptions with which Mr. Giles prefaced his remarks, and he presumed all the other members would do the same, for it was not only desirable that the Pharmaceutical Society should be officially represented as regards the construction of the Pharmacopœia, but they had a right to demand that position. Mr. Giles saw that their body was wandering in the wilderness of official Pharmacopœia neglect, and this resolution was to him a pillar of cloud by day and a pillar of fire by night which should lead them to the desired Canaan of official Pharmacopœia recognition. But, much as he sympathized with that, with one part of the resolution he could not agree, and that was the introduction of a system of co-operative research work, a system which would very much imperil if not entirely destroy the existence of individual research. It would be putting forward a forced and exotic plant in place of the strong indigenous plant of private individual work. He did not say that all men engaged in research would put forward this objection; but would there not be many who would say, Why should I spend trouble and time in doing work that is provided for by the Society in its official laboratory? Mr. Giles saw no other way of accomplishing the result, but with all deference he would point out another. If it were necessary that an additional incentive should be given to pharmaceutical research it might be done by offering good prizes for essays on certain subjects which were supposed at the time to specially require investigation. In that way a number of good papers would be obtained which would be adjudicated upon by the Committee, and the prizes awarded to the best men. But certainly if the majority of members present did not wish to give a crushing blow to individual research they might amend the resolution by suggesting that the Council be requested to consider the advisibility of offering prizes for researches.

The Vice-President thought they were much indebted to Mr. Giles for having brought forward this subject. In one sense there was great opportuneness in it, although it was inopportune in another, for it came before them at a time when their thoughts were prominently directed to their recognition in connection with the National Pharmacopœia. That question would be shortly before the House of Commons, when he trusted the collective energy of the members of the Society would be put forth to such a degree as would compel recognition. His own impression was that there was an almost entire consensus of opinion amongst the profession as to their rights. One or two medical men on the previous evening had expressed to him their astonishment that their claims had not been conceded before. He took it Mr. Giles wished them to direct their attention especially to pharmaceutical works, though he used the phrase original research, which covered a much larger extent of ground. But he differed from him as to his suggestion for a laboratory, which he feared would, as had been pointed out by Mr. Luff, tend very considerably to repress individual energy.

The President said this matter had not come before the Council in such a way that any definite conclusion had been come to, because it was felt desirable to hear Mr. Giles's interpretation of his own resolution. He would remind the meeting that it was not necessary to discuss details at the present moment; the first point was, did they want to commit the incoming Council to set to work on these lines? and if so, was this the best time to do it? Every educated pharmacist must thoroughly concur in the spirit of the resolution, but he did not think it was at all opportune, and should have much preferred if it could have been kept altogether from the public gaze for another year or two. It had two aspects, one, the simple one in which Mr. Giles presented it, that of true pharmaceutical research, and no doubt there was a great deal of good work which might be done in various ways without stifling individual energy. There was a deal of work which could only be done in such a way as had been sketched out; for instance, such a matter as was referred to by Mr. Ekin could not possibly be done by individuals. Nevertheless he did not believe that providing very great facilities for research necessarily tended to promote its advancement. But he would rather not discuss those details; the object of the resolution evidently was to move the Council on to advance pharmacy. But the present Council, and he was quite sure the incoming Council, was anxious to do so, and it had power to do all that was required without coming to the Annual Meeting for instructions. Requests made to a public body, either to the Conference or to the Society, with regard to original work in pharmacy had been practically few and far between. As to the institution of medals, prizes and things of that kind, he did not think they would be so satisfactory as the plan Mr. Giles recommended. But the resolution had another aspect, and that was a political one. There was a certain Bill now going through Parliament which deeply interested them, and in that aspect it was unfortunate that the resolution should have come forward. As it had come forward he was bound to ask the members to reject it, unless Mr. Giles, as he hoped, would withdraw it, not because they disapproved of it, but because it was most distinctly inopportune. He thought Mr. Giles might very well content himself with the expressions of opinion he had heard, and with the fact that there was likely to be on the new Council a certain number of men who entirely sympathized with him in spirit. They might depend upon it that when the time came he for one should not be slow to move in the direction he had referred to. There could be no better way of spending money than in the promotion of the object contemplated; but because at that particular moment such a resolution would perhaps be misunderstood, and might have a bad effect on the minds of the medical profession, and might even be regarded by some of their own body as somewhat of a slur on the Council, he would ask the meeting to join with him in urging on Mr. Giles and Mr. Martindale to withdraw both the motion and the amendment.

Mr. Giles said he would at once respond to that request, and he could only say that if he had had any idea of this objection the resolution would never have seen the light. He had not the slightest idea that he was acting contrary to the wishes of the President, or he would not have moved in the matter, and, in fact, he had expressed a wish to see the President before the notice was published, but had not been able to do so. He had heard quite enough to satisfy him that this motion would have better success in his hands than it would in his own, and he was quite content to leave it there. One or two things had been said which were a little debateable on which he would not enter, and would only say this, that the observations made might be divided under two heads, those who went against the laboratory part of the scheme, which was merely an incidental suggestion, those who went against the resolution; but if he dismissed all who went against the laboratory, which was merely an incidental matter, he did not know what there would be left to answer.

Mr. Lomas thought sufficient notice had hardly been taken of the slight put upon members of the Society by the way in which the new Pharmacopœia was being prepared. If he was rightly informed the Committee had come to the professors of the Society, and having done so he thought it was rather remiss of those gentlemen not to have mentioned the President and Council of the Society as being the most proper persons to assist them in the forthcoming Pharmacopœia.

The PRESIDENT said he had reason to know that that course had been recommended by the professors; but it was obviously not within their power to compel those who were engaging them as professional experts to follow their advice.

Mr. MARTINDALE having expressed his willingness to withdraw the amendment,

The PRESIDENT said it was very gratifying to find both gentlemen so ready to accede to the suggestion made. The Council had already shown that it was capable of dealing with large questions and of spending money when required on good objects. When the opportune time came no doubt the then Council would face this question in the best interests of pharmacy. Although it was important that they should be represented on the Pharmacopœia Committee, he hoped they were not going to neglect pharmacy because they were not so represented. It would be their duty to advance pharmacy as much in the future as they had endeavoured to do in the past, and by all available means.

Mr. VIZER asked if any approach had been made to the medical profession itself with regard to the Pharmacopœia Committee. The Bill was now in the House, and it seemed to him a very opportune time to make their influence felt amongst members of Parliament who at the present time might be anxious to do what they could to support them. He believed if the medical profession were directly approached by the agency of the local secretaries they would receive a large amount of support.

The PRESIDENT said this idea had not been lost sight of, and they were preparing to make use of their medical friends in the way suggested. In fact, last August something was attempted in that way, though, unfortunately, very few medical men were then in town.

Mr. URWICK suggested that deputations should wait on members of Parliament; a deputation told better than letters, and letters better than printed forms.

Mr. SYMES said when they were getting signatures last autumn on this question, forms of petition were prepared for signature by medical men and he obtained some. He spoke to a great number of medical men on the subject and did not remember one who disagreed with the view he put forward; but when he presented the petition he found very great difficulty in getting signatures, because they did not like to sign anything which appeared to be against the wishes of the Medical Council.

Mr. MACKENZIE said this question of representation on the Pharmacopœia Committee was really the burning question of the day. He had hardly any faith in getting much through the medium of medical men, and would rather advocate going direct to members of Parliament. Last year, a deputation waited on the Scotch members, when he was told by a very prominent member, the highest legal authority in Scotland, that if they wanted to get what they had a right to have, and which he was surprised they had not, they must try to influence their individual members in counties and boroughs. He said that he would use his influence with his friend who had charge of the Bill, and he could not see how a reasonable man could refuse to grant their request. This appeared to be a very opportune time for pressing this question upon the various members of Parliament.

Mr. WARD (Sheffield) endorsed the remarks of Mr. Symes with regard to the difficulty of getting medical men to sign petitions. As local secretary he waited on the leading physician in Sheffield last year, who expressed much sympathy with his object; but when he presented the petition he told him he was pledged to the present Bill, and could not sign anything against it. After that, of course, he knew it would be perfectly useless to go to any other medical man in the town.

Mr. ALLEN said his experience was quite the reverse of that of Mr. Symes and Mr. Ward. He had taken occasion to call on a few practitioners in London and obtained signatures from all, except one, whom he called upon.

The PRESIDENT said there was no doubt the sympathy of the medical profession was with them, and where signatures were refused it was from the fear that in signing a petition of that sort they would be opposing their own Bill, and medical men were naturally anxious not to interpose any difficulty in getting that Bill through Parliament.

The VICE-PRESIDENT remarked that with regard to this question of approaching medical men, no doubt experiences had been diverse, but the great value of the signatures of medical men was to influence members of Parliament.

Twenty-five gentlemen were then appointed scrutineers of the balloting papers.

Mr. GILES then proposed a vote of thanks to the President for his courtesy in presiding on that occasion, and to the Council for the manner in which they discharged their important duties during the past year.

Mr. HOWARD HALL seconded the motion, which was carried unanimously.

The PRESIDENT called attention to the registers placed upon the table, pursuant to Act of Parliament.

The meeting then adjourned until Friday at 12 o'clock, to receive the report of the Scrutineers.

ADJOURNED GENERAL MEETING.

Friday, May 23, 1884.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The adjourned meeting for receiving the report of the Scrutineers was held on Friday, May 23.

The Chairman of the Scrutineers read the following report:—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers, appointed at the Forty-third Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:—

Voting papers reported by the Secretary to have been issued	3672	
Voting papers received	1287	
Voting papers issued but not returned		2385
Voting papers received		1287
Voting papers disallowed:—		
Informal	18	
Received by post too late	62	
	—	80
Voting papers registered		1207

Result of the Poll.

Atkins	1092	Robbins	899
Schacht	1067	Butt	863
Greenish	1044	Squire	855
Savage	1036	Borland	848
Radley	988		
Woolley	985	Shapley	594
Gostling	980	Young (John R.)	551
Churchill	974	Dyer	524
Young (Jas. R.)	951	Baldock	510
Williams	943		

GEORGE S. TAYLOR, *Chairman.*

Chas. J. Mead.	Chas. B. Allen.
Edwd. B. Stamp.	W. Pickard.
I. Bourdas.	Jas. T. Tupholme.
David Hooper.	J. W. Bowen.
J. Horncastle.	M. Mitchell Bird.
Alfred E. Tanner.	Philip Princep.
Robt. Rowe.	Pelham C. Maitland.
W. H Symons.	John Morris Broad.
Geo. F. Bindloss.	Wm. Gulliver.
Wm. Matthews.	Henry Mathews.
T. Edwd. Greenish.	R. Fisher Young.
Robt. Saml. Bathe.	T. Howard Hall.

The New Council.

The Chairman then declared that the following gentlemen would constitute the Council for the ensuing year:—

Andrews, Frederick, 34, Leinster Terrace, Hyde Park, W.

Atkins, Samuel Ralph, Market Place, Salisbury.

Borland, John, 7, King Street, Kilmarnock.

Bottle, Alexander, 37, Townwall Street, Dover.

Butt, Edward Northway, 13, Curzon Street, Mayfair, W.

Carteighe, Michael, 180, New Bond Street, W.

Churchill, Walter John, 46, New Street, Birmingham.

Gostling, Thomas Preston, Market Hill, Diss.

Greenish, Thomas, 20, New Street, Dorset Square, N.W.

Hampson, Robert, 205, St. John Street Road, E.C.

Hills, Walter, 225, Oxford Street, W.

Radley, William Valentine, 42, Hampton Road, Southport.

Richardson, J. G. F., Elmfield, Stoneygate, Leicester.

Robbins, John, 147, Oxford Street, W.

Savage, William Dawson, 4, Park Road East, Brighton.

Schacht, Geo. F., 52, Royal York Crescent, Clifton, Bristol.

Squire, Peter Wyatt, 413, Oxford Street, W.

Symes, Charles, 14, Hardman Street, Liverpool.

Williams, John, 16, Cross Street, Hatton Garden, E.C.

Woolley, George Stephen, 69, Market Street, Manchester.

Young, James Robertson, 17, North Bridge, Edinburgh.

Auditors.

There being only the requisite number of candidates (five) for the office of Auditors, the Chairman declared the following duly elected for the ensuing twelve months:—

Hodgkinson, William 198, Upper Whitecross Street, E.C.

Hopkin, William King, 16, Cross Street, Hatton Garden, E.C.

Lescher, Frank Harwood, 60, Bartholomew Close, E.C.

Stacey, Samuel Lloyd, 300, High Holborn, W.C.

Watts, William Manning, 32, Lower Whitcross Street, E.C.

The meeting concluded with a vote of thanks to the Scrutineers for their services.

BOTANICAL PRIZE FOR 1885.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom, between the first day of May, 1884, and the first day of June, 1885; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Merit, will be given at the discretion of the Council. In the event of none of the collections possessing sufficient merit to justify the Council in awarding medals or certificates, none will be given.

Competitors must be Associates or Apprentices or Students of the Society, and under twenty-one years of age.

The collection must consist of phanerogamous plants and ferns, arranged according to the natural system of De Candolle, or any other natural method in common use, and be accompanied by lists, arranged according to the same method, with the species numbered.

The collector must follow some work on British botany (such as that of Babington or Hooker), and state the work he adopts. The name of each plant, its habitat, and the date of collection must be stated on the paper on which it is preserved.

Each collection must be accompanied by a note, containing a declaration signed by the collector, and certified by his employer, or a pharmaceutical chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1884, and the first day of June, 1885, and were named and arranged without any other assistance than that derived from books.

In estimating the merits of the collections, not only will the number of specimens be taken into account, but also their rarity or otherwise, and the manner in which they are preserved, and should a specimen be wrongly named, this will be erased from the list.

The collection must be forwarded to the Secretary of the Society, 17, Bloomsbury Square, on or before the first day of July, 1885, indorsed "Herbarium for Competition for the Botanical Prize." After the Prize Distribution in October, collections will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collector, if required.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly stated meeting of this Society, was summoned for Wednesday, May 7, at three o'clock, but did not take place, owing to there not being a quorum present. Six members, including the President and Vice President, attended; but as the regulations require that no business shall be transacted unless seven members be present, there was no meeting.

Chemists and Druggists' Trade Association of Great Britain.

The Annual Meeting of this Association was held on Tuesday, the 20th inst., at the Inns of Court Hotel. The proceedings commenced as usual with a

MEETING OF THE GENERAL COMMITTEE

at 11 o'clock. Mr. John Harrison (Sunderland), President, in the chair.

The Secretary read several letters from members regretting their inability to be present, one of which made some remarks as to the financial management of the Society and the mode of audit, which were explained by Mr. Haydon.

The Report, of which the following is an abstract, and Financial Statement were taken as read.

The Report of the Executive Committee stated that the Association had successfully defended three of its members in the law courts during the past year in summonses issued against them under the Sale of Food and Drugs Act. The cases, which were referred to in detail, have already been published in this Journal. Since the last Annual Meeting the Executive had been compelled to refuse to defend one of the members in proceedings under this statute, on account of his having refused to accept the sealed sample of the drug purchased when offered at the time of purchase by the inspector. The Executive therefore took the opportunity of again impressing upon all members of the trade the advisability of invariably accepting samples when offered by inspectors under the Act, as refusal to do so places them in a very unfortunate position in the event of proceedings being commenced, and may, as in the case referred to, prevent the Association placing the services of their solicitor at the disposal of the defendant. During the past year proceedings had been successfully taken by the Association against four persons residing in Birmingham, London, Oldham, and Peterborough, for infringements of the 17th section of the Pharmacy Act, and it was stated that since the formation of the Association in October, 1876, the solicitor and officials had succeeded in convicting thirty-six illegal traders residing in all parts of the country under that section of the Act. Full reports of the hearing of these cases have appeared from time to time in the trade journals. Cases of illegal trading in poisons are, however, frequently brought before the Executive in which the requirements of the 17th section of the statute as to the labelling of the article have been complied with. In such cases the Association is powerless to institute legal proceedings against the offender under the 15th section for the sale of such poisons, power to sue under that section being, by the provisions of the Act, vested solely in the Council and Registrar of the Pharmaceutical Society. The Report then went on to say that no statute directly affecting the interests of chemists and druggists had been passed since the last Annual General Meeting, but the Executive had, nevertheless, given watchful attention to the proceedings of Parliament. The Bill introduced into the House of Lords last Session dealing with the amendment of the Medical Acts had been again brought into that House and passed during the present Session, and would probably at an early date be placed before the Commons. No action had been taken on the part of the Executive in regard to this Bill, as it contains no provision inimical to the trade, and expressly stated that:—"Nothing in this Act contained shall in anyway prejudice or affect the lawful occupation or business of chemists, or druggists, or, so far as relates to selling, compounding or dispensing medicines, the rights, privileges or employment of duly licensed apothecaries in Ireland." A Bill to restrict the sale of patent medicines had been introduced into the House of Commons in February last, by Mr. Warton and Dr. Farquharson, but was thrown out on the second reading by a large majority. In accordance with the instructions contained in a resolution passed by the last Annual General Meeting of the members of the Association, the Executive had considered the advisability of approaching the Council of the Pharmaceutical Society, with a view to united action in support of an amended Pharmacy Bill, and at their meeting on September 7th last, instructed the Secretary to write to the Secretary and Registrar of the Pharmaceutical Society, to arrange an interview between the Pharmaceutical Council and a deputation from the Executive of the Association before the introduction of such a Bill into Parliament. An interview was arranged, and took place on November 6th last. The proceedings, at the request of the President of the Pharmaceutical Society, were not reported. At the interview, a long discussion took place on the amendments proposed by your Executive to the draft Pharmacy Bill prepared by the Pharmaceutical Council, when it was ascertained that the Council had already settled the lines of the measure with the Privy Council. At the subsequent request of the President of the Pharmaceutical Society, the President and Vice-President of the Association again met the Law and Parliamentary Committee of the Pharmaceutical Council in reference to the matter, and eventually the Executive, at a meeting held on February 8th last, passed two resolutions to the effect that a small deputation should be appointed to accompany a deputation from the Council of the Pharmaceutical Society to the Lord President of the Privy Council in support of legislation on the general basis of the Bill now in the hands of the Government, and that the deputation should consist of the President, Vice-President, Mr. Barclay and the Secretary. These resolutions were in due course communicated to the Secretary and Registrar of the Pharmaceutical Society, who subsequently received a letter from the Privy Council Office, stating that Her Majesty's Government had decided to confine the Bill which they proposed to introduce to the question of the sale of poisons, and not to include in that Bill any amendments of the Pharmacy Act in relation to the status or the organization of the Pharmaceutical Society, and that the Lord President, after the Government Bill had been introduced, would be willing to receive a deputation on the subject. In compliance with a resolution passed at the last Annual General Meeting directing that a memorial, signed by the officers of the Association, should be presented to the House of Commons in support of the claim of pharmacists to be associated with members of the medical profession in a legally constituted committee for the purpose of preparing the British Pharmacopœia, and instructing the Executive to take such steps as they thought desirable in the matter, a petition had been drawn up and presented to the House of Commons by the Right Honourable Joseph Chamberlain, President of the Board of Trade, and a print of the same had been transmitted to all Local Secretaries of the Association, with a circular, asking them to request their parliamentary representatives to support its prayer in the house. Two cases having come under the notice of the Executive in which members of the Association had been threatened with prosecutions by the Inland Revenue authorities for having sold, as finish, methylated spirit, said to contain an insufficient quantity of gum resin, although the members themselves maintained that the spirit, when sold, met the requirements of the general order of the Board in that particular, the Executive applied for an interview between the Commissioners of Inland Revenue and a deputation from the Executive Committee of the Association, for the purpose of urging upon the Inland Revenue authorities the advisability of issuing an order making it compulsory on excise officers when purchasing spirit for analysis to leave with the seller a portion of the spirit sold. The Commissioners of Inland Revenue having expressed their willingness to receive the deputation, an interview took place and the Vice-Chairman of the Board, promised that the wishes of the deputation should be complied with. A General Order to that effect had since been issued to Excise officers throughout the country. At the Annual Meeting of the Scottish Branch, ten members had been nominated and duly elected by the Executive at their meeting held on May 21st last. The Executive regrets to report that the strength of the Association had declined during the past year, the total number of members on the Register at the time being 3340. It was thought there was no doubt that this was attributable to the severe and long continued depression in trade, which had so seriously affected many societies depending for support on voluntary contributions. The financial statement would show that 2632 annual subscriptions, and £68 13*s.* in donations have been received during the year, as against 2743 annual subscriptions and £63 4*s.* 6*d.* in donations during the previous financial year. The total expenditure during the same time had decreased from £903 9*s.* 3*d.* in the financial year, terminating April 15th, 1883, to £774 10*s.* 9*d.* during the present financial year.

The financial statement from 16th April, 1883, to 15th April, 1884, was as follows:—

Mr. Urwick moved the adoption of the Report and Financial Statement. He said the only thing to be regretted was that members of the trade did not support the Association better. If it were not for that Association chemists and druggists would often be in a very unfortunate position, the Pharmaceutical Society not seeing its way to defend persons who were prosecuted, though it appeared to him that it might fairly subscribe towards the expenses of such cases.

Mr. Mackenzie (Edinburgh), in seconding the motion, said chemists and druggists ought to look upon this Association as a peace of mind insurance society, and it was a great pity it was not more appreciated.

Mr. Cross (Vice-President) said the value of organization was not sufficiently understood amongst chemists; but it must be remembered that they were engaged in an onerous occupation, which demanded their constant attention, and this led them to let outside things alone. The difficulty which both the Pharmaceutical Society and their own body had always had when dealing with the constituted authorities was that they did not directly represent the whole body of chemists, only a fractional part being subscribers. When this Association was started, the idea was to enlist the whole body in the kingdom, the subscription being fixed at the lowest point with that view. The result though favourable was not so much so as was hoped, and to-day, after several years' existence, they stood in a worse position than they did to begin with. Still, though it was disappointing, he saw no reason for despair; he believed there had been no time when chemists had been more harassed and worried than they were now, and it seemed to him, therefore, inevitable that they would awake to their own interests and the necessity of protecting them. If any burning question were to arise, no doubt they would quickly respond, and the apparent apathy would disappear. The Report was very interesting, and he hoped it would be carefully studied; the only matter to which he would specially refer was the proposed legislation. The Executive had discussed this matter with the Pharmaceutical Council under the gravest sense of responsibility, and as those very moderate proposals had not been accepted by the Government, he hoped a much stronger Bill would be brought forward and pushed to a successful conclusion.

The President, in putting the motion, made a few remarks on the financial position of the Association, which was not at all satisfactory, the expenditure having exceeded the income. He wished to draw special attention to the large amount of subscriptions in arrear, and hoped that the members of the Committee would each in his own district endeavour to get these arrears paid up; if this were done there would be a surplus on the year of over £100. He must take exception to the remark of the Vice-President that the Association was in a worse position than when they began. They were certainly poorer, but they were not worse, for they had a history behind them and could show for the money which had been expended, a large amount of work. If, as Mr. Mackenzie had suggested, the Association secured peace of mind to the members, it did an immense good, and perhaps it was the sense of security which prevailed which accounted for the apparent apathy which they all deplored.

The motion was then put and carried unanimously.

Messrs. Laird, Bingley and Arblaster having been appointed scrutineers of the ballot papers for the nomination of the Executive,

Mr. Ellinor (Sheffield) moved that the Committee recommend for adoption the amendment in Rule 6, of which Mr. Jervis had given notice, viz., that Rule 6 be amended to read as follows:—"The Executive Committee shall consist of twenty-four members, to be elected by ballot at each Annual Meeting. Five members to form a quorum. It shall be the duty of the General Committee to prepare and recommend to the Annual Meeting a list of the names of members to serve on the Executive Committee for the ensuing year. A President, a Vice-President, a Treasurer and an Honorary Secretary shall be elected by and from the Executive Committee."

Mr. Mackenzie seconded the motion.

Mr. Alderman Maltby opposed the motion on the ground mainly that it would detract from the interest felt in the Annual Meetings, if the election of President were not decided there. At the same time he should be glad if nominations were made so that the members might know something more about the matter than they now did.

Mr. Urwick also opposed the motion, because he thought the present rule worked very well, and it was a pity to alter it.

Mr. Barclay (Birmingham) thought it desirable that as much power as possible should be placed in the hands of the trade; he was opposed to the Executive doing anything which could be done by the members at large.

Mr. Mackenzie asked, if a system of nominations were adopted as suggested, any one could be elected President or Vice-President who had not been nominated.

The President said he thought the existing rule would allow of nomination being made, as the decision would still remain with the members, and would be taken by ballot.

Mr. Symes (Liverpool) hoped Mr. Jervis would not press his motion.

The Vice-President (Mr. Cross) opposed the motion. He thought it better that the President and Vice-President should be able to speak as elected by a large constituency rather than as the officers of an Executive.

Mr. Vizer supported the motion.

Mr. Jervis admitted that the rule had worked well up to the present, but they had been very fortunate in their officers, and the same good fortune might not always attend them; and he contended that the Executive were much better able to select good officers than the members at large.

Mr. Hampson said he had been much disposed to support the motion at first, but on further consideration, and after hearing what had been said by other gentlemen, he did not think it would be opportune to press it at the present moment.

After a few words from the President in favour of the present state of things, the motion was put to the vote, and negatived by 11 votes to 4.

The Scrutineers having made their report, the Committee adjourned to the General Meeting.

General Meeting.

The Annual Meeting took place at half-past twelve o'clock, Mr. John Harrison, President, in the chair.

The attendance was somewhat meagre.

The Chairman, in moving the adoption of the Report, expressed his regret that the attendance was so small. He was very sorry to find that so few members found it consistent with their duties to be present at the Annual Meeting, when matters connected with the trade were to be discussed, and he was more surprised because from time to time they heard great injury was being done to the trade, and that united action was required, and yet when opportunity for discussing these matters and of providing a remedy was afforded only a small number availed themselves of it. It might possibly be said that this showed perfect satisfaction on the part of the trade with the work the Association was doing. If it were otherwise members would come to the meeting to call the Executive to account, so that the fact of their absence might be taken as indicating general satisfaction with the work which was done. A *résumé* of that work would be found in the Report, and he might say that every case brought forward which, in the judgment of the Committee, seemed to be one which should be defended had been undertaken, and he was proud to think that they had been so remarkably successful. It showed in the first instance that chemists had been unduly pressed by the authorities, and in the second place that the Executive exercised due care with regard to the case presented to them. It was not necessary to specify the particular nature of the case, but he might refer to one in which their old friend the milk of sulphur was brought forward. Probably the gentleman who brought it up must have thought that the Association was defunct or asleep, but with his usual ill-luck he had failed. If anything could prove more conclusively than another the necessity for such an institution, it was that now and again these cases would crop up, and he might very fairly say that if that Association were not in existence and prepared to defend members there would very soon be great cause for dissatisfaction. The Committee called attention, and very properly so, to one matter which had arisen probably in reference to these cases, viz., the refusal on the part of some chemists when a purchase was made for the purpose of analysis to receive the sealed sample, and he would urge on all members whenever this was done not to do so, because it placed the society in a great difficulty and the vendor also. He could understand that a man might feel so thoroughly in the right that it was like making himself an accessory after the fact to receive the sample at all; but that was not the way to look at it. He must remember that the reception of the sample enabled him to prove before an independent authority that the articles he sold were perfectly genuine, and it also showed that in his own mind he was so convinced that he had only done what was right that he was willing and anxious to retain a proof of it in his own hands. Proceedings had also been taken against traders in various parts of the country, which had been uniformly successful. Whenever the Committee had received information that illegal trading had been carried on, if they found there was a reasonable prospect of success in taking up those cases they never failed to do so. The next matter referred to in the Report was the proceedings in Parliament. First, in reference to the Bill which was introduced in the House of Lords last year for the amendment of the Medical Act, as it contained nothing prejudicial to their interests no action was needed. The second Bill was one for regulating the sale of patent medicines, introduced by Mr. Warton, but that came to an untimely end. The most important matter, no doubt, was the proposal for the amendment of the Pharmacy Act, and on that he should wish to say a few words. At the last Annual Meeting, a resolution was passed that it was desirable that united action should take place between the Pharmaceutical Society and themselves, if possible, to obtain such an amendment of the Pharmacy Act. The Pharmacy Act was then before them, and had received very full and fair discussion. Possibly had they been in possession of more information, that discussion might have been shorter, and much that was said might have been omitted; but they proceeded then on the principle that the measure was before them then for discussion, and were not aware that the details had been settled beyond all controversy. He then took occasion to remark that if these lines had been laid down by a superior authority, as a loyal subject, he should be prepared to accept them, but he was under the impression that the Bill had been brought before the Council of the Pharmaceutical Society in the character of experts who had been asked to frame a Bill for the better prevention of accidents by poisoning, and that they were asked to give their opinion as to what that method should be, and he considered the Bill then before them was the answer of the Pharmaceutical Society to that proposition. It was found afterwards that that was not the case; that although they had been asked to bring in such a Bill, they had also been restricted as to its nature, and that certain clauses had been inserted by a superior authority carrying out the views of the meeting. The Executive sought an interview with the Privy Council, when they learnt for the first time definitely the real state of the case. There was much in the Bill with which they did not both agree; there were several points on which they were in thorough agreement; there were some points they considered objectionable, while there were several others which they thought very valuable, for instance, the restriction of dispensing, and the sale of patent medicines containing poisons to chemists and druggists, and the proposition that the law should apply to companies as well as individuals. These were matters of the greatest possible importance, and, therefore, although there were other points with which they did not agree, they felt it was a Bill which they ought to support, as those on which they differed were the very points which had been settled by a higher power. There were three courses open to them, either to assume the position of actual hostility, and to go to the Privy Council and to Parliament and oppose the Bill, tooth and nail; to take up a position of perfect neutrality, saying to the Pharmaceutical Society, We have had no part in framing this Bill, and you must take all the responsibility of it yourselves; or, thirdly, they might say that there was much in it which they agreed with, and, therefore, although there were other points on which they did not, they would support the Bill for the sake of the important advantages it contained. The Executive decided on the latter course, as he believed very wisely. He should not have liked to stand there to-day and have to excuse himself and his colleagues for the fact that no legislation was attempted when there was such a general feeling that legislation was required. He should not like to stand there in the character of an obstructionist, and, therefore, he accepted what was good and swallowed as best he could what he did not like. The lesson to be drawn from the proceedings which led up to the Act of 1868 ought not to be forgotten. That Act was rendered, to a large extent, useless by the divisions which existed in their own ranks, and that weighed very considerably with the Executive, because they felt that if they took up a position of hostility the Government would say, Here are two bodies, representing, to a large extent, the same people, coming to totally different opinions on the same question, and the result would have been that they would have said, "Gentlemen, you had better go home and settle these differences amongst yourselves, and in the meantime we will legislate as we think proper." What had actually taken place? Last year a bill was brought forward in the House of Lords with regard to a Pharmacopœia Committee and on that bill their claims were entirely ignored. The Council of the Pharmaceutical Society and their own Executive took measures to petition the House of Commons with a view to providing that chemists and druggists should be represented on that Committee. Nothing could be fairer in principle, and, in fact, it had been acknowledged to him by several members of Parliament that the claim appeared to be thoroughly reasonable, and that unless there was some very good reason to the contrary, it would have to be considered. Everyone seemed to think there must be something mis-stated or omitted, or their claims would have been recognized before. However, although they made this strong and joint representation, showing no division in their ranks, the Bill had been re-introduced and their claims were again ignored. To his mind, nothing could prove more conclusively the necessity for union, for if they were ignored when they were united, what would be their position when, on the one hand, the Pharmaceutical Society advocated one thing, and they, on the other hand, another? Their great necessity was organization. An old Hebrew hero was represented as saying, "Justice with courage is a thousand men;" but had he lived now he would have said, justice with organized force is a thousand men. Unless they were thoroughly organized and worked well together it was no use indulging in wild declamations as to nothing being done, for nothing could be done. But if they could go forward to the country and to Government and say they spoke in the name of ten thousand men who were determined to have justice done to them there would be a very different response. He hoped every chemist and druggist would bear in mind that if they wanted a Pharmacy Act which would be of any use, which would give them that justice which they had a right to demand, that demand must go straight to the Government from a united people. What was the extent of the support they received at present? They only spoke in the name of scarcely three thousand members. This was a sad reflection on the times and showed a want of appreciation amongst chemists which, to say the least of it, was disastrous to their interests. There was nothing else special in the Report to which he need allude, except one matter which was brought forward at the last meeting, the question of selling methylated spirit; that was brought forward in consequence of several complaints made with reference to the purchase of finish having been made which was found, after a considerable lapse of time, not to contain the quantity of resin which it ought, and the Executive were requested to seek an interview with the Inland Revenue authorities on the subject. In due time a special deputation waited on the authorities at Somerset House, where they were received with great courtesy, and so thoroughly convinced were the authorities with the few observations made by the deputation that they at once said they would recommend the Board to issue the order which was asked for. Nothing could prove more conclusively that if they could unite themselves together with the view of obtaining justice, it would not be long withheld. Another matter to which he wished to refer was the strength of the Association. That was discussed by the Committee on the previous evening, when it was pointed out they were strongest where there were active local secretaries, and he would, therefore, suggest that if there were any local secretaries present who were not active that they should either become active at once, or if they could not do so, resign in favour of someone else who could. Every man in his own district should bring the claims of the Association forward with the view to increasing their numerical strength, for it was only in that way they could go forward, and speak with power and effect.

The Vice-President (Mr. Cross) seconded the motion, and said he had very few remarks to offer except to emphasize what had been already said by the President. With regard to the works of the Association, both of attack and defence, the fewness of the cases which had been undertaken argued in favour of the policy hitherto adopted; for if the Association had not done its work well there would no doubt have been many more. But, in fact, there had been no cases come before the Committee which had not received full attention. With regard to the sealed samples also of articles purchased for analysis, however indignant an innocent man might feel, he should remember the object for which the sample was furnished to him, and also that his refusal to receive it might be attributed to very different motives. With regard to the revised edition of the Pharmacopœia the organization stood them in good stead, for although the result of their action was *nil*, he believed their position was considerably improved. Several members of Parliament were communicated with, and from personal interviews he had with them, he believed that the justice of their claims had largely impressed them, for when the time came the matter could be taken up where it was then left, and be carried on with success. With regard to the deputation to the Inland Revenue, it was very gratifying to hear Mr. Adam Young say that the Inland Revenue authorities wished as much as possible that the sale of methylated spirit should be in the hands of chemists and druggists, because they were a body of men in whom the authorities had confidence.

Mr. Whittle regretted the constant decrease in the numbers of the members of the Association, and was astonished to find that chemists did not to a greater extent support a society which they knew was so valuable and was ready to come forward at any moment and defend them when they were unjustly attacked. He feared, however, that too many of them did not care who paid the expenses so long as they did not, and fancied they were quite as safe as if they subscribed. He contended, however, that they were not safe in their present position, for the Association ought to have at least £500 to £1000 in hand. It would never do to take up a case which they could not go through with. He had never met a single chemist who did not think the Society had done marvellous work for the amount of money it had received; but, unfortunately, chemists and druggists were about the weakest specimens on the face of the earth, though if united they might do some good. Many of them were like the pendulum of a clock, they went from their shop to bed, and from their bed to the shop, and would never spend 5*s.* for anything unless they could get an immediate 7*s.* 6*d.* They lost the sale of patent medicines through the same parsimony; they wanted to have the privilege for nothing, and thought two guineas was too much. They got it down to 5*s.*, and now they had to a great extent lost the trade; and serve them right. It was the want of unity which was their great weakness. They would never get a Pharmacy Act which would do them any good unless they stood shoulder to shoulder and showed the public they were an educated body of men who had confidence in themselves. Many persons looked upon this Association as a sort of double of the Pharmaceutical Society, and all the more since several members of the Executive were also on the Council. No doubt those gentlemen worked well in both Societies, but it had occurred to him that it would be as well if the two bodies were kept more distinct, and if the members of their Executive were not members of the Pharmaceutical Council.

Mr. Walker (Coventry) said no doubt the remarks just made were intended in the most friendly spirit, but as a member of the late Executive he must say that those gentlemen who were also on the Council of the Pharmaceutical Society had been of the greatest possible use to the Trade Association, and instead of doing anything to suggest that they were simply nominees of the Pharmaceutical Society, they had always taken the greatest possible interest in trade matters, and had given many very valuable hints with reference to the possibilities of the train of thought which the Pharmaceutical Society might take on any given subject. Hence their presence, instead of being an element of weakness, had been positively a source of strength. With reference to the cases which had been taken up, as the President had said they had always done their best to take up a case when there was any chance of success, and that no doubt was true, and he might add that every case was carefully considered on its merits. Burns said we only know the evil done, but never what is resisted, and if members knew the number of cases which came before the Executive and which were carefully considered, they would feel sure that the Executive were not by any means deaf to the requests which reached them from all quarters. As a member of the wholesale trade he often heard reports that the Executive had not sufficiently attended to the interests of trade; that they had not taken up this, that and the other case. But he could only say that all such reports were founded on an entire misconception, and that if any case were not taken up there were very good reasons for it.

Mr. Hampson said he was one of those unfortunate members of the Executive who happened to be a member of the Pharmaceutical Council. He believed that the fact that members of that Council had also been on the Executive had been a decided advantage. It might not be without alloy, for there were very few things in this life free from alloy. He must express great satisfaction with the opening address of the President. It had an excellent ring of strength about it, and he hoped if it did not reach every chemist's shop in the kingdom it would at any rate reach a great many, and would meet with the response it deserved. He regretted that the meeting was so small, and also that the strength of the Association was not greater, but other organizations suffered from the same state of indifference. It was a universal complaint, but on the other hand it ought to make them more determined to utilize to the utmost the strength that they had. Although they were not numerous they were representative, and if they used the strength they possessed at the right time they would be able to make themselves felt. If he had any special interest with regard to this Association, it was that they should on all possible occasions work harmoniously with the Pharmaceutical Society. He knew that the Pharmaceutical Society was not without fault, that it had done many things which it ought not to have done, and on the other hand it had not done many things it ought to have done. But what was the cause? Just the same as they had to complain of there, the want of support from outside, the want of the invigorating agency which the members gave, and which ought to be given in a much greater measure to both Societies. On the other hand, the Pharmaceutical Society was a fact, its position was most important with regard to pharmacy, and this Association might on all occasions without loss of dignity unite with the older Society in carrying out all worthy objects. He was extremely gratified to find that within the last year the two Societies had approached each other. He might almost say they had shaken hands. At any rate there was a friendly feeling; the old feeling of distrust was gradually vanishing, and in a short time the two Societies might be able to work each in its own manner without any feeling of suspicion or jealousy. He was much struck with the point made by the President, when he referred to the fact that notwithstanding their united action with regard to the Pharmacopœia, they did not seem to have made themselves felt; to a certain extent that was true, but he believed they had made themselves felt. There was another Medical Bill in the House of Lords, and they would have another opportunity of exercising their power, and if they did so in conjunction with the Pharmaceutical Society he thought they might obtain a just recognition at the hands of the Legislature. If any other reason were needed for uniting and for increasing the strength of the Association, there was the fact that the Government were about to legislate with regard to the sale of poisons, for notwithstanding that the Pharmaceutical Society had had the ear of the Medical Department of the Privy Council, and had had numerous conferences, it had up to the present time utterly ignored their representations. That appeared to be a melancholy state of things, and they might have to oppose the Patent Medicine Bill; very likely they would. Surely that was another reason for uniting their strength and acting harmoniously with the elder body.

Mr. Mackenzie (Edinburgh) having been on the Executive from the very first, said he could speak with the fullest confidence as to the advantage which had been derived from the presence of gentlemen who were on the Council of the Pharmaceutical Society. At the early meetings they looked upon it as a fortunate day when they had the presence of those who were not sent from the Pharmaceutical Society to the Trade Association, but rather from the Trade Association to the Council of the Pharmaceutical Society, and if they would analyse the voting papers from year to year, he thought it would be found that those members who stood highest on the poll were not those who had least to do with the Trade Association, but rather the reverse. He hoped that any misunderstanding which might exist on that point would be corrected, and that these gentlemen would remain on both Boards for a long time to come. With regard to the Pharmacopœia they must cease to look to high quarters for patronage or support, and rely more upon themselves. Each of them represented districts widely scattered, from all of which members were returned to Parliament, and their influence would be best used by communicating directly with those members. After the last meeting he went to the House of Commons, and saw the Lord Advocate, who acknowledged that their position was a very strong one, and advised him to see other members, which he did, and explained the true position of matters, so that he believed they would get a good deal of support when the time came. The day might not be far distant when these gentlemen would be wanting votes again, and that was a very favourable time to produce an impression upon them. If there were apathy in the trade he believed it arose from their success; and if they were to resolve to wind up the Association, there would be an immediate outcry all over the country.

Mr. Allen (Kilburn) remarked that though gentlemen from the country came up in great force the Londoners kept behind their counters and would not attend. One gentleman had alluded to the good which might be done by local secretaries, and he understood that the London Committee were considering whether district secretaries should not be appointed in London who should endeavour to induce more members to join. Almost the first paragraph of the report related to an important prosecution in the North of London, and with regard to that he might mention another good result of organization, which was not stated in the report. Three highly respectable members of the trade were summoned by the analyst connected with the Hampstead Vestry, but in each case, by the help of the *Referee* and the efforts which the Executive put forth, the prosecution broke down. Shortly afterwards a circular was sent round bearing the signatures of the three prosecuted members, referring to the fact that the appointment of the analyst was with them, and urging chemists and druggists in the neighbourhood to oppose his appointment. He appended his own signature and saw one or two members of the Hampstead Vestry on the subject, and the result was that shortly afterwards another gentleman was appointed.

Mr. Barclay said the past year was one in which they had been able to do very little, but they would have done more had their hands not been tied, to a great extent, by the Pharmacy Bill. He, for one, did not feel at all sorry that this Bill had received its *coup de grace*, and that they might now start *de novo*, for they might very easily get a better Bill than the one which was proposed to be introduced. Professor Attfield, whom he was glad to see present, in the remarkably able address which he gave as President of the Pharmaceutical Congress, had laid down some lines on which chemists might set to work to try to obtain legislation. The advantage which would have been obtained by the trade had the Pharmacy Bill passed in its entirety would have been but very small, and he thought if they boldly set to work and made up their minds as to what they ought to have, and go to the country and use their influence with members of Parliament and the public, they might do a great deal better than they had reason to expect from the past. Something had been said about organization, and they were supposed to know something about that in Birmingham; but he might say that Birmingham organization was powerful because of the large numbers at its back. It was easy to organize if you had numbers, but it was difficult and useless to obtain an organization if you had nothing to organize with. They ought all to endeavour to obtain a large increase of numbers in face of the legislation Government was about to introduce, which would probably not be very satisfactory, and, therefore, they might anticipate the necessity for fighting which would no doubt stimulate all the local secretaries to go to work. As the Chairman had said, they could not agree with the Pharmacy Bill on all points, but it was a question whether they should take it in its entirety, stand aside altogether, or oppose it, and they felt that they could not take the responsibility of dividing the trade, and hence they supported the Bill. He should be very glad if the meeting would come to some practical conclusions, so that the incoming Executive might be able to gather the opinions of the chemists throughout the country as to the lines on which they should endeavour to act. In the proposed Bill certain poisons were to be termed poisonous, and were to be allowed to be sold by anyone if properly labelled. This was a question which chemists ought to look at very seriously. He thought it would be a retrograde step altogether to allow other persons to sell poisons under these restrictions. If it were once admitted, the schedule of poisonous articles would be continually added to by the Privy Council, and chemists would in the end be seriously injured. The public mind was made up pretty generally to go for something more than the Pharmacy Bill had attempted, to give the chemists more powers, and to place around strong medicines, as well as poisonous medicines, restrictions in favour of chemists. He thought it would be well if a resolution were passed for the Executive to endeavour to obtain the opinion of chemists throughout the country as to the lines of a Bill, and to approach the Pharmaceutical Society, stating their views, and endeavour to arrive at harmonious and united language. They must be united if they were to do anything at all, but, at the same time, being a distinct association, they might help the Society a great deal more if they were allowed. It was quite impossible for the Executive to fight for a bill which was not its own, and it could only be its own if it commanded the sympathies of the Executive, which it would not do thoroughly unless the Executive had some hand in framing it. He was glad to find that the Pharmaceutical Society and that Association were more in harmony than they had ever been in the past, and trusted they would continue so, but if they were to pursue a common course and assist each other, there ought not only to be united action, but common ground on which they were to work. He was sorry to see that the strength of the Association had gone down, but still there was no need to despair. During the eight years of its existence something like £8000 had been raised, and a great deal had been done for it, and seeing these successes in the past he trusted chemists would not be so blind as to allow the Association to expire.

Mr. Symes, of Liverpool, feared some of the remarks made as to the numerical strength of the Association would look as if they were ringing its death knell, but he trusted that was not the case. He looked around to see what others were doing as the best means of bringing the trade together, and stemming the downward course which it seemed to be running. If they looked to the Continent they found that their pharmacy was more of a science, and was not so much regarded from a trade point of view, so that their experience would not be exactly applicable; but their brethren in America were very much in the same condition as themselves. They were harrassed by co-operative societies, and by certain black sheep amongst their own body who were known by the popular name of "scalpers." All sorts of means had been devised for dealing with these difficulties and for giving a healthier tone to the commercial character of pharmacy, and restoring something like a prosperous condition to the business. After proposing several methods of boycotting the persons who supplied these "scalpers," and forming co-operative societies amongst themselves, they had fallen back on exactly the same course as had been adopted in this country of forming a national trade association, in which the most substantial and most thoughtful men reposed the greatest confidence for getting over their difficulties. It seemed to him that just at the time when they had come to a low point in their history it was rather encouraging to find that people like the Americans, who were proverbially cute, could devise no better method than the one which had been adopted here for eight years for bringing the trade together.

Mr. Vizer remarked that fire insurance offices always regarded conflagrations as one of the best things which could happen to them, because when a large establishment was burnt down, a lot of small ones rushed in to insure. It seemed to him that they wanted something of the same kind in order to stir up their brethren to come forward and join the Society. If he recollected rightly the Association had its origin almost in the embers of a large conflagration which occurred some years ago. He saw Mr. Haydon shake his head, but at any rate at that time a large number of chemists united in consequence of the great excitement that existed in order to meet a common evil. It seemed to him that when prosecutions were brought against chemists at the present time, disagreeable as it might be to the individual, it did good to the Association, because it led men to see there was danger ahead. When he was local secretary in Brighton, he took a great deal of trouble, and there was not a chemist in the town who was not either written to or spoken to on the subject; but the greatest obstacle he met with was the idea that there was no danger immediately threatening them. With regard to representation on the Pharmacopœia Committee, it occurred to him that something might be done by approaching the medical profession on the subject, for his experience was that as a body, they would support the presence of chemists upon that Committee. He thought if the medical profession were approached in the proper manner a great power might be brought to bear on the Government by which their end might be attained. He rejoiced at the harmonious spirit which existed between that Association and the Pharmaceutical Society, and there was certainly no reason why they should be antagonistic.

Mr. Haydon said he could not agree that the Association was founded on the embers of any other.

Mr. Diaper said in his view the Pharmacy Act Amendment Bill proposed by the Pharmaceutical Society was such an emasculated one that it was not worth supporting, but if they put forward one founded on the lines set forth by Professor Attfield it would be enthusiastically supported.

The President thought Mr. Vizer had rather confused the birth of that Association with the former one, the United Society of Chemists and Druggists. The origin of the Association really was the unfair prosecution by public analysts and the unfair attacks by the medical profession; these matters led to the formation of this Association for the reasons stated in rule 2, namely, "the protection of the legitimate interests of chemists and druggists from unfair attacks and encroachments and the promotion of their common welfare."

The resolution was then put and carried unanimously.

Mr. Jervis, being called upon to move the resolution which stood in his name, said that as there had been a considerable discussion on this matter in the General Committee, and as he found that the time had not come in the opinion of many members for introducing the amendment he proposed in rule 6, he should withdraw it.

Election of the Executive Committee.

The Secretary having read the following list of names which had been recommended by the General Committee for election as the Executive for the ensuing year, it was moved by Mr. Allen (Kilburn) and seconded by Mr. Kay (Stockport) and carried unanimously that they be elected.

Andrews, Frederick, London.	Maltby, J., Lincoln.
Arblaster, C. J., Birmingham.	Parker, W. H., Nottingham.
Barclay, Thomas, Birmingham.	Pasmore, G., Exeter.
Bell, C. B., Hull.	Southall, William, Birmingham.
Chapman, Henry, Scarborough.	Symes, Charles, Liverpool.
Churchill, W. J., Birmingham.	Walker, G., Coventry.
Cross, W. G., Shrewsbury.	Williams, F. P., Manchester.
Davis, H., Leamington.	Yewdall, E., Leeds.
Ellinor, G., Sheffield.	
Hampson, Robert, London.	*Scotland.*
Harrison, John, Sunderland.	Ettles, John, Elgin.
Holdsworth, T. W., Birmingham.	Laird, G. H., Edinburgh.
Jervis, W., Sheffield.	Mackenzie, James, Edinburgh.

Mr. Alderman Maltby (Lincoln) begged leave in accordance with the opinion which had been expressed at the meeting of the General Committee to nominate Mr. Harrison as President for the ensuing year.

Mr. Barclay (Birmingham) seconded the nomination.

Mr. Bell (Hull) then nominated Mr. Cross as Vice-President, which Mr. Jervis seconded.

Mr. Hampson proposed and Mr. Andrews seconded the nomination of Mr. Southall as Treasurer.

Mr. Ellinor moved and Mr. Symes seconded the re-appointment of Mr. W. J. Churchill as Honorary Secretary.

Messrs. Lance, Whittle and Candy were appointed Scrutineers of the ballot papers.

During the examination of the voting papers Mr. Kay (Stockport) drew attention to the question as to the use of the royal arms, and stated that he understood that its legality would be tried: that although the Solicitor-General said that the prohibition of the use of the royal arms was not intended to apply to chemists who had it over their shops, he had reason to believe that the Lord Chamberlain believed it to be his duty to prevent its use as much as he could.

Mr. Symes said he had given some attention to this subject, and he believed the legal position to be this—the introduction of the clause in question arose from the fact of patent agents, especially, using the royal arms over their door as a means of misleading the public and inducing them to believe that they had some Government appointment. It was the determination of the promoters of the Bill in question to prevent such a thing being done; but as long as the arms were used merely as an ornament and not in any way to mislead the public, he thought there would be no danger of prosecution.

Mr. Andrews said there was no doubt the use of the royal arms had been much abused, especially in the neighbourhood of London, and it was much safer to discontinue it.

Mr. Allen suggested that it would be well for the Executive to watch the publication of the *Trade Marks Journal*, for he feared many labels at the present time were getting on the Register, which, to a certain extent, seemed to be limiting the use of the English language, and unless some body like the Trades Association took it upon themselves to watch the matter, it would be possible to register a name such as "Jockey Club," which would be very inconvenient to the trade at large. Some persons claimed the use of the word "tablets," which had been used almost from time immemorial, and he knew of persons having been threatened with prosecution for using that word.

Mr. Haydon said some four years ago he accepted the office of Secretary to the Birmingham Exchange and Chamber of Commerce, and in that capacity he had a great deal to do with trade marks. It was quite impossible for any such words as "Jockey Club" to become a trade mark. "Jenner's Liver Mixture" had been registered as a trade mark, but not simply the words, but in combination with a distinctive outline and device, and in the same way "Jockey Club" in a distinctive device might be registered, but the trade mark would not consist in the words "Jockey Club," but in the device which those words included. With regard to the word "tablets" having been registered by a firm who claim the exclusive right to do so he might say that they took pretty good care not to carry that contention into a court of law. The matter had been considered by the Executive, and if any member of the Association were threatened with an action for the use of that word he believed the Association would be prepared to defend him.

Mr. Barclay said it was possible formerly to register words as a trade mark, but now there must be a design.

Mr. Allen said that if any gentleman who was threatened upon such grounds would write to the Association he would be informed whether he had good grounds of defence or not. If the Association were to undertake the watching of the Trade Mark Register it would necessitate a vast amount of work, because it would involve the reading up and carefully indexing of the whole of the marks already registered, which would be a work of great magnitude.

The scrutineers here reported that the following officers had been elected:—

President, Mr. John Harrison; Vice-President, Mr. W. G. Cross; Treasurer, Mr. William Southall; Hon. Secretary, W. J. Churchill; and, on the motion of Mr. Maltby, seconded by Mr. Laird, of Edinburgh, they were appointed accordingly.

The President and Vice-President having briefly expressed their acknowledgments of the honour which had been conferred upon them, the proceedings terminated with a vote of thanks to the President for his conduct in the chair.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

The Dissolved Oxygen of Water.

A lecture of some interest, owing to its relation to the sewage question, was delivered by Professor Odling before the Royal Institution on Friday, the 16th inst., under the title of "The Dissolved Oxygen of Water." Since the discovery of the weight of the atmosphere in 1640, and the difference in weight of the so-called fixed air, inflamable air and vital air, now known respectively as carbonic acid gas, hydrogen, and oxygen, Faraday has shown that the atmosphere is nothing else than the gas of a liquid, which gas by a sufficient abstraction of heat could be reduced to a liquid state. In 1823 he also reduced many of the known gases to a liquid state, and some tubes containing gases liquefied by Faraday were exhibited by the lecturer. Three methods may be used for the liquefaction of gases; by a lowering of the temperature, by pressure, or by making a solution with water, or a combination of these methods. The solubility of different gases in water was shown by Professor Odling in a tabular statement; at a temperature of 15° C., 2 volumes of hydrogen, 1½ of nitrogen, or 3 of oxygen are dissolved in 100 volumes of water, whilst 4356 volumes of sulphurous acid, 45,780 volumes of hydrochloric acid gas, or 78,270 volumes of ammonia are dissolved in the same volume of water. An increase of solubility is obtained with a reduction of temperature, though the rate of increase differs with the gas, that of sulphurous acid increasing at about five times the rate of that of hydrochloric acid. Professor Odling then stated that at a summer temperature of 70° F. water contained 1·8 cubic inches of oxygen per gallon, and 2·2 cubic inches at the winter temperature of 45° F., equivalent to four to five grains of oxygen per cubic foot. From calculations based upon this data it will be seen that at a temperature of 70° F. there are 2·58 tons of oxygen in every ten million cubic feet of water, increasing to 3·16 tons at the temperature of 45° F., thus showing a difference of over half a ton per ten million cubic feet between the summer and winter temperatures. It has been computed that during dry weather sixty four-million cubic feet of water pass Teddington Lock, which would contain seventeen and a quarter tons of oxygen; by the time this volume of water has reached Somerset House it is found to have lost from twelve to thirteen tons of the oxygen, which must have been taken up in the oxidation of sewage matter. In some experiments made by Dr. Tidy in June, the water from Teddington to Battersea showed an average percentage of aëration of 78, as compared with possible aëration; at Greenwich 38 per cent., and at Purfleet 26. Experiments carried on from July to November by Dibdin and Dupré showed that the percentage of aëration at Richmond was 86, decreasing to 40 per cent. at Woolwich, and as low as 24 per cent. at Erith, but by the time the water had reached Southend it had nearly recovered its first aëration, showing a percentage of 75. Dupré also made some experiments at Erith which showed a range of 50 percentage of aëration at high water to 40 percentage at low water, and results obtained by Dr. Tidy on the Colne confirmed these conclusions. It has been calculated that if a volume of water containing 35 per cent. of sewage matter be allowed to flow for one mile exposed to the air, the whole of the sewage would become oxidized. It has also been found by experiment that a closed vessel containing water with 5 per cent. sewage gives only 32 per cent. of aëration on the fourth day as compared with 84 per cent. on the day when introduced into the vessel. The results of these experiments tend to show that although no doubt the self-purifying power of the water of the river is sometimes overtaxed, it still retains the power of oxidizing the sewage matter, but the question as to whether it has the power of ridding itself of living bacteria still remains to be solved. During the lecture Professor Odling incidentally mentioned that the old method of ascertaining the quantity of oxygen present in water, by boiling in a vacuum and analysing the gas evolved, had been completely superseded by the use of a hyposulphite, introduced by Schutzenberger, of Paris. This compound not only acts as an oxidizing agent but also as a deoxidizer, speedily decolorizing indigo, magenta, iodide of starch, etc. As the colour is not destroyed until all the oxygen has been absorbed by the hyposulphite the amount of oxygen can be readily ascertained by the use of a burette.

Parliamentary and Law Proceedings.

Illegal Sale of Poison.

Before the county magistrates at Exeter, on Tuesday, the 20th inst., Thomas Elliott Pitt, agent and dealer, was summoned for selling half an ounce of strychnine, on April 20, at Kenton. Mr. Friend prosecuted and Mr. Brown defended.

Mr. Friend said that the proceedings were taken under the 31st and 32nd Vic., chap. 121, section 17, which stated that poison should be labelled when sold, and the person buying the same should leave his signature and address with the seller. On April 20, in consequence of the loss of a number of domestic animals, the police at Starcross had been spoken to on the subject. They made inquiries, and found that half an ounce of strychnine had been sold to a gamekeeper by the defendant, who is a grocer and ironmonger, and it appears that the poison was tied loosely to a packet of groceries which was sent to the gamekeeper. Mr. Friend did not know how it was the defendant was a chemist and grocer in one, but he was. The penalty for a first offence was £5, and in a second case £10.

Mr. Brown pleaded guilty on behalf of the defendant, and said that the gamekeeper had promised to come and sign the book, but he had failed to keep his promise, and the police had come upon the defendant. The bottle of poison had not been opened, and he asked the magistrates to dismiss from their minds the fact that animals had been poisoned through any act of the defendant.

The Bench fined the defendant £2 and £1 0*s.* 3*d.* costs.

ANSWERS TO CORRESPONDENTS.

David.—(1) *Vaccinium Vitis-Idæa.* (2) Probably *Achillea Millefolium*, but it is impossible to say with certainty with only a fragment of a leaf.

J. Humphrey.—(1) *Sanicula europæa.* (2) *Polygala vulgaris.* (3) *Poterium sanguisorba.* (4) *Orchis mascula.*

Australian.—The Board of Examiners has no power under the Pharmacy Act to accept the diploma referred to in lieu of any part of the examination.

Communications, Letters, etc., have been received from Messrs. Smith, Moore, Lloyd, Page, Bear, Bennett, Dymock, Shepperson, Brookes, Braithwaite, Christy, Foot, J. H. A.

"THE MONTH."

Messrs. Heckel and Schlagdenhauffen have recently (*Comptes Rendus*, April 21, p. 996) investigated the chemical constituents of the bark known as "bois piquant" in Cayenne, and "clavalier jaune ou épineux" in the Antilles. The bark of this plant has been used for some years in the south of France, and particularly at Marseilles, as a febrifuge. It is derived from *Zanthoxylum Caribæum*, Lk., and *Z. Perrottettii*, DC., which is regarded by the authors as only a variety of the former. The bark has been described accurately by Guibourt ('Hist. des Drogues,' 6th ed.), who confounded it with that of *Z. Clava-Herculis*. It bears some resemblance to cusparia bark in appearance, but its microscopic structure is quite different. The authors have obtained from the bark a crystalline principle in colourless needles, soluble in alcohol, and represented by the formula $C_{12}H_{24}O$. It is not coloured by contact with concentrated nitric, hydrochloric or sulphuric acid, and melts at 285° C. The bark also yields an alkaloid in minute quantity, of which the formula is promised when a larger quantity has been obtained. It is prepared by digesting with water an extract made from the alcoholic solution left after removal of the crystals, treating the aqueous solution with lime, evaporating to dryness and exhausting the residue with boiling alcohol. This alkaloid is coloured bright red by nitric acid, but it differs from brucine in the fact that the nitric solution evaporated on a water-bath and treated with a drop of solution of stannous chloride does not assume a violet colour, while concentrated sulphuric acid colours it blue and an alcoholic solution of bromine gives with it a blue coloration lasting for a long time. The aqueous solution of the alkaloid in the dose of ·005 gram administered hypodermically to a frog caused a rapid general paralysis, the respiratory and circulatory functions gradually ceasing and death ensuing in half an hour. Similar effects were produced on guinea pigs and rabbits. The authors have also obtained from the bark a substance of resinous aspect (amorphous alkaloid?), of alkaloidal character and producing similar effects in similar doses. It is soluble in water. The bark itself gives, when macerated in water, a yellow, bitter, slightly acid infusion, which is turned brown by ferric chloride and a bright red by nitric acid, and gives yellow precipitates with mercuric chloride, stannous chloride, tannin, picric acid, the double iodides and phosphomolybdic acid.

Although boldo has been known to contain an alkaloid since 1876, when Messrs. Bourgoin and Verne detected boldine, the base was obtained in such a small quantity that it seemed doubtful if the medicinal properties of the plant were due entirely to it. This doubt has recently given rise to a fresh investigation by M. P. Chapoteaut (*Comptes Rendus*, xcviii., 1052), who has found that boldo also yields a glucoside. This is extracted by making an alcoholic extract of the leaves, treating it with water acidulated with hydrochloric acid, so as to completely eliminate the alkaloid, and after freeing the liquid from mucilaginous matter as much as possible, shaking it with ether or chloroform. On evaporation a syrupy transparent body is left, of a yellowish tint and having an aromatic odour and taste. A kilogram of the leaves yields about three grams of the glucoside. On analysis it gave results corresponding to the formula $C_{30}H_{52}O_8$. Heated with very dilute hydrochloric acid, it was found to split up into glucose and a body of a syrupy consistence, soluble in alcohol and benzine, but insoluble in water, and represented by the formula $C_{19}H_{28}O_3$. The glucoside is considered by the author to be an ether in which glucose plays the part of an acid. The physiological effects of the glucoside have been studied by Dr. Laborde, who finds that when introduced into the body, either by hypodermic injections (tried on guinea pigs) or by the mouth (tried on dogs), it produces rapidly a tranquil sleep, lasting a longer or shorter time in proportion to the dose; from this sleep the animals awake in a natural manner and without any appreciable effect on their appetite, health, or habits. When subcutaneously injected into the dog, Dr. Laborde has observed that this glucoside excites and augments the secretory functions, causing an increase in the amount of bile, saliva, and urine. The results thus obtained seem to indicate that a very valuable addition has been made to the list of useful hypnotics and cholagogues. The bark of the shrub forms an article of commerce in South America, and it would, perhaps, be worthy of investigation if the glucoside be contained in larger quantity in it than in the leaves.

In a memoir published a few months since (*Journ. Ph. et de Chim.*, [5], viii., 5), Messrs. Regnauld and Villejean gave their reasons, based upon chemical analysis, for believing that the product at that time supplied to surgeons under the name of chloride of methylene was often, if not always, a simple mixture of chloroform and methylic alcohol. Subsequently, with a view of pursuing the subject physiologically, they prepared what they claim to have been pure chloride of methylene, the action of which was tested on dogs and other animals, comparative experiments being also made with chloroform. They report (*Journ. Ph. et de Chim.*, [5], x., 384) that the results confirm their previous belief and that the misnamed mixtures owe their properties to chloroform only. The physiological action of chloride of methylene was found to differ entirely from that of chloroform, except that both compounds produce insensibility. But the symptoms resulting from the inhalation of chloride of methylene (CH_2Cl_2)—contractions of the muscles, clonic movements, epileptiform and choreic seizures—were so constant and of such an alarming character that the authors think its employment as an anæsthetic during surgical questions is out of the question, and they doubt if it has ever been so employed.

In connection with this last expression of opinion, however, it may be mentioned that Dr. B. W. Richardson, in a note in the last number of the *Asclepiad* on the administration of chloroform and methylene bichloride, expressly refers to the contraction of muscular fibre produced by all anæsthetics of the chlorine series. This, he says, he is in the habit of counteracting by the administration of four to six fluid drachms of pure ethylic alcohol (sp. gr. 0·830) mixed with eight ounces of water, at a temperature of 95° to 100° F., about twenty minutes before the chloroform or bichloride of methylene is to be inhaled.

Ammoniated chloroform is recommended by Dr. B. W. Richardson (*Asclepiad*, p. 156) for the temporary preservation of *post-mortem* specimens. A fluid drachm is introduced into a wide-mouthed bottle of sixteen to twenty ounces capacity, previously filled with coal gas, and the bottle is then closed with a stopper coated with glycerine, until required for use. Ammoniated chloroform is also used by Dr. Richardson as an inhalation to reduce pyrexia. It is prepared by mixing together equal parts of strong alcoholic solution of ammonia and chloroform, the small quantity of water that separates after a time being removed by means of bibulous paper. The compound is described as a clear, pleasant-smelling liquid, with much less pungency than ammonia. About two drachms are placed in the inhaler, and gradually breathed during half an hour. The inhalation may be repeated as often as required, and carried on until the narcotic action of the chloroform is clearly but not deeply manifested.

Another subject mentioned by Dr. Richardson (*Asclepiad*, p. 165) is the internal administration of amyl nitrite, which he speaks of as advantageous in some cases, especially in asthma. The most convenient formula he has found to be as follows:—

Amyl nitrite, pure, ...	♏xxxvj.
Ethylic alcohol (sp. gr. 0·830), .	ʒvj.
Pure glycerine, to	℥jss.

Dose, 1 fluid drachm in a wineglassful of warm water, to be swallowed slowly and repeated every two or three hours if necessary.

A new variety of menthol is likely to be placed on the American market during the coming summer. A sample of the crystals, which have been presented to the Museum of the Society, have the same crystalline form as the Japanese menthol and are white and dry, but have an odour quite different, resembling that of the American oil of peppermint. Mr. A. M. Todd, of Nottawa, Michigan, claims to have discovered a process for obtaining this menthol in crystals from the oil of *Mentha piperita* in sufficient quantity to meet public requirements. A sample of the menthol is in the hands of Professor Flückiger for examination, who will doubtless publish any results that he may arrive at in due course. Mr. Todd considers, as the result of his experience during seventeen years in the distillation of oil of peppermint, that the tests for its purity are not accurately known, or, at all events, are not accurately given in the United States Pharmacopœia. He finds in the oil a resinous principle which hinders the crystallization of the menthol, and in order to obtain the menthol easily, the oil needs careful rectification. By forcing sprays of steam through it and by recondensation, its crystallizing tendency is considerably increased. The price of this menthol from the true peppermint is likely to be about 50*s*. per pound.

Herr Dieterich states that an emplastrum adhæsivum c. iodoformo has met with much acceptance in Germany, it being prepared of two strengths, one containing 20 and the other 30 per cent. of iodoform. This plaster, if applied directly to the previously cleansed surface in the case of slight burns and small wounds, is said to cause a very rapid healing. According to the same authority an addition of salicylic acid to ordinary "lip salve," and a previous treatment of the almond oil used with benzoin, increase the healing powers of the ointment.

Being convinced of the advantage of presenting phosphate of lime to the stomach in the gelatinous form, rather than in the pulverulent form to which it is usually brought for convenience of washing, M. Tanret sought for a plan by which the monocalcic phosphate should be treated with just a sufficiency of slaked lime to convert it into tricalcic phosphate (*Journ. Pharm. Chim.*, [5], ix., 389). This he effects by mixing with the solution of acid phosphate the molecular proportion of lime dissolved by the aid of sugar. He finds that practically to obtain a given quantity of gelatinous phosphate the proportions to be taken are the same quantity of acid phosphate and half as much slaked lime.

The German Pharmacopœia orders the removal of the oil from powdered ergot by means of ether. Messrs. Denzel and Wacker having examined the oil so removed (*Archiv*, xxii., 314) found it to contain ecbolin, one of the active constituents of ergot; they therefore think the official instructions defective. A similar result was obtained when carbon bisulphide was used. On the other hand, with benzine or light petroleum spirit a very pure oil was obtained, free from any trace of ecbolin. The superiority of light petroleum spirit for this purpose is also affirmed by Herr Dieterich, who further recommends the same solvent for removing the oil from the powders of henbane, sabadilla, staphisagria and mustard seeds, as well as from cochineal.

Bearing in mind the varying composition of many tannin compounds, and considering that the reasons that sometimes call for their use do not exist in the case of "cannabinum tannicum," Herr Bombelon was induced to prepare some pure cannabinum by treating the tannin compound with zinc oxide. He obtained it as a greenish-brown powder, not agglutinating upon exposure to the air, and volatilizing without residue from platinum foil. In doses of 0·05 to 0·10 gram it produced sleep without previous excitement, whilst cannabinum tannicum was found to act more unequally and require higher doses. "Pure cannabinum," prepared in this way, is described (*Pharm. Zeit.*, May 10) as tasteless, insoluble in water, and readily soluble in alcohol, ether and chloroform. As the best vehicle Herr Bombelon uses pulv. coffeæ tost., or pulv. cacao exoleat., and it is given as a powder, in pills or as an emulsion.

The use of corrosive sublimate as an antiseptic is rapidly increasing. Dr. P. Negri who has used it extensively in the Maternity Hospital, at Novare, states (*Practitioner*, p. 377) that the toxic effects of a solution of 1 part in 1500 or 2000 is almost *nil*; in one case only he observed slight mercurial exanthema. He considers that the weaker solution is sufficiently strong to prevent puerperal sepsis, and that it will completely replace that of the 2 per cent. solution of carbolic acid, over which it has the advantage of being cheaper and of having no odour.

Sulphate of copper is also being used with success as an antiseptic in obstetric practice (*Med. Times*, May, 24, p. 207). The solution is used of a strength of 1 per cent., and is warmed before use to 36 to 38° C. It possesses the advantage of having no odour, not causing discoloration like perchloride of iron, while possessing similar astringent and coagulating properties, and if employed several times in the twenty-four hours during eight or ten days it has no other effect than slowing the pulse and lowering the temperature.

In the *Lancet* (May 3, p. 795), Mr. S. Gamgee, consulting surgeon to the Queen's Hospital, Birmingham, describes a substitute for sponge which he has invented, and which combines absorbing power with elasticity, while it is cheap enough to be burnt after use. This he proposes to make permanently antiseptic by enclosing a thin ball in the centre containing any desired antiseptic, which could be set free by cracking the capsule with a squeeze. The chief constituents of the artificial sponge are cocoa-nut fibre and absorbent cotton. These sponges are said to absorb sixteen to eighteen times their weight of fluid, and readily fill and squeeze out again like an ordinary sponge.

The value of crushed ice as a dressing for burns and scalds, first pointed out by Sir James Earle, is confirmed by Dr. Richardson (*Asclepiad*, 164). The ice after being reduced by crushing or scraping to a fine state of division, as dry as possible, is mixed with fresh lard into a paste, which is placed in a thin cambric bag and laid upon the burn. This is said to banish all pain until the mixture has so far melted that a fresh dressing is necessary.

Having accidentally received some splashes of brown fuming nitric acid upon the skin of the face, and reasoning that the action of the acid was one of intense oxidation, Mr. Irving tried the effect of a dilute solution of sulphurous acid that happened to be available, and he describes it (*Chem. News*, May 2) as astounding. The action of the nitric acid seemed to be immediately arrested, and the pain removed, whilst the wound healed afterwards very rapidly.

In a comparison of the notices hitherto occurring in literature of nonylic acids (pelargonic acids) of various origin there is a certain degree of correspondence observable, but not such to warrant any conclusions as to their identity. Herr Bergmann was, therefore, induced to prepare and compare samples of nonylic acid (1) from the normal octyl alcohol of heracleum oil, (2) by oxidation of oleic acid, (3) by oxidation of methyl-nonyl ketone, (4) from the distillate of the leaves of *Pelargonium roseum*, (5) from the fusel oil of beet molasses, and (6) from undecylenic acid. The results obtained, which the author describes in detail, as well as the methods of preparation (*Archiv*, xi., 331), leave scarcely any doubt that the six different products were all identical with one another.

In an interesting contribution to the "histo-chemistry" of plants (*Monatshefte*, v., 94) Herr Rosoll illustrates the light that can be thrown upon vegetable principles by studying them microchemically *in situ* in the plant. The first plant mentioned is the *Helichrysum bracteatum*, the yellow flower heads of which are well known as a variety of "everlasting flowers." This yellow colour is very persistent, but when the dried flower heads are dipped in borax solution to which hydrochloric acid has been added, the involucral leaflets become a beautiful ruby-red colour. Further investigation showed this yellow pigment to be a hitherto undescribed quinone-like substance, which Herr Rossoll has named "helichrysin." In the younger leaflets it exists in combination with protoplasm, whilst in the older leaflets it has its seat in the residual cell contents. Helichrysin is soluble in water, alcohol, ether and organic acids; insoluble in benzol, chloroform and carbon bisulphide; is coloured purple-red by mineral acids and alkalies; and is precipitated by metallic oxides and their salts as a red coloured extract. The same body appears to be present in *H. orientale*, *H. fœtidum* and *Statice Bonduelli*. Passing to the fungi, the organs of fructification of the *Peziza aurantia*, with their yellow disk and lighter outer side, were examined. It was found that the orange colour is due to a new yellow pigment, that has been named "pezizin," which is present in the form of extremely minute drops combined with an oil-like substance that occurs dissolved in the plasma of the paraphyses. The pigment, which occurs also in *P. convexula*, may be dissolved out by alchol or ether. Saponin was ascertained to occur in the living roots of *Saponaria officinalis* and *Gypsophila Struthium*, dissolved in the cell juice, from which it can be separated in small amorphous white particles by treatment of thin slices of the root with absolute alcohol or ether. In the dried roots and in quillaia bark it occurs as an amorphous white or grey substance. By treatment with concentrated sulphuric acid and exposure to air, which gives rise first to a yellow, then a bright red and afterwards a beautiful blue-violet colour, saponin can be detected in the contents of all the cells of the parenchyma of the middle bark, the medullary rays and wood parenchyma of the fresh and dried roots, as well as in the contents of all the parenchyma cells of the middle bark of *Quillaia saponaria*. But the most interesting of these observations from a pharmaceutical point of view was one establishing that strychnine occurs in the seeds of *Strychnos Nux-Vomica* and *S. potatorum* dissolved in oil droplets suspended in the contents of the endosperm cells.

As a microchemical test for solanine, Herr Schaarschmidt lays the section to be examined in moderately concentrated sulphuric or nitric acid and then brings it under the microscope, when in a few seconds the presence of the alkaloid is marked by a beautiful rose colour (*Chem. Zeit.*, May 11). In this way the author recognized the presence of solanine in *Solanum tuberosum*, where the principal seat of the alkaloid is in the stalk, and especially in the tuber; also in *S. nigrum*, *S. Dulcamara*, *Capsicum annuum*, *Lycopersicum esculentum* and *Mandragora officinalis*.

In attempting to introduce hydrogen into the coniine molecule ($C_8H_{17}N$) to form octylamine ($C_8H_{19}N$), by distillation of the dry hydrochlorate with zinc dust, Dr. A. W. Hofmann found that hydrogen was given off instead, and a new base formed, having the composition represented by the formula $C_8H_{11}N$, and standing in the same relation to coniine as pyridine to piperidine (*Ber. Berl. Akad.*, 1884, 161). This base, which has been named "conyrine," is a colourless liquid, showing a beautiful blue fluorescence, lighter than water, boiling at 168° to 170° C., and having an odour resembling pyridine and picoline, but less pungent. When oxidized by means of solution of permanganate, conyrine yielded pyridinmonocarbonic acid (*Berichte*, xvii., 825). This and other considerations pointed to the probability that conyrine was orthopropylpyridine, while coniine was orthopropylpiperidine, or orthopropylpyridine hexahydride. An attempt was therefore made to regenerate coniine from conyrine, which was completely successful, and it therefore only remains to convert pyridine into orthopropylpyridine (conyrine), which, probably, will not be difficult, to complete the synthesis of coniine.

Ordinary commercial sulphuric acid seldom contains more than 96 per cent. of sulphuric monohydrate (H_2SO_4), and only exceptionally 98 per cent., since the acid is decomposed by the heat required for evaporation at about this degree of concentration. But it is reported that at Griesheim, in Germany, it has been found that the monohydrate can be obtained in crystals on the manufacturing scale by submitting the "acid" to a sufficient degree of cold (98 per cent. to a little below 0° C., and 96 and 97 per cent. to about −10° C.). The first crystallization still retains some mother-liquor, but the pure monohydrate is obtained by melting the crystals and repeating the operation. The reduction of temperature due to heat becoming latent in the liquefaction of the crystals is utilized to cool a further quantity of crystals.

Dr. Olszewski has determined the solidifying temperature of several of the gases that Faraday failed to solidify in consequence of not being able to produce a sufficiently low temperature (*Monatshefte*, v., 127). The refrigerating medium used by Dr. Olszewzki was liquid ethylene, in conjunction with an air pump, by which means he was able to reduce the temperature, if required, to −139° C. At −102° C., under ordinary pressure, chlorine formed an orange liquid, in which there was a separation of yellow crystals, and at a lower temperature the whole liquid formed a yellow crystalline mass. At the same temperature hydrochloric acid gas formed a colourless liquid, which solidified at −115·7° C. to a white crystalline mass that began to melt again at −112·5° C. Arseniuretted hydrogen also formed at −102° C. a colourless liquid and a white crystalline mass at −118·9° C., melting again at −113·5° C. Ethylic ether, freed from alcohol and water, solidified at 129° C. to a white crystalline mass, which passed again into a liquid at −117·4° C. Pure amylic alcohol formed at −102° C. an oily liquid, had the consistence of soft butter at −115° C., and froze at −134° C. to a hard semi-transparent body.

Dr. Phipson records the observation (*Chem. News*, May 2) that the odour of ether which appeared to be given off by lemons after having been kept for a time in a damp cupboard was coincident with the development of *Aspergillus glaucus* upon them. He thinks the odour is due to the breaking up of citric ether (triethylic citrate) under the influence of the fungus, and makes a suggestion as to what probably takes place. Under the influence of warmth and moisture some of the sugar in the ripe lemon undergoes fermentation, and the alcohol formed combines immediately with citric acid to form triethylic citrate, which is split up by the fungus into free ether, which is volatilized, carbonic acid, and, probably, other intermediate products. It may be remembered that in a communication to this Journal some years since ([3], v., 201), Mr. F. M. Rimmington attributed the development of an odour of acetic ether in some concentrated infusion of quassia to the formation of acetate of ethyl under the influence of cryptogamic life.

In a recent communication to the Asiatic Society of Japan (*Nature*, April 24), Mr. O. Korschelt gave some very interesting information respecting the constituents of Japanese lacquer. He considers the raw lacquer juice to be an emulsion which contains a peculiar acid (urushic acid), a gum, a nitrogenous body, water and traces of a volatile acid. The hardening of the juice that takes place when it is exposed in a thin layer to moist air at a temperature between 20° C. and 27° C. is due to the oxidation of urushic acid to oxyurushic acid under the influence of the nitrogenous body, which acts as a ferment. Whilst the gum is useful in maintaining the condition of an emulsion, its presence in the hardened lacquer is injurious, as it gives rise to blisters in contact with water. The reduction of the proportion of gum by the admixture of raw juice with separated urushic acid is, therefore, advantageous; but on the other hand, if this admixture be carried beyond five parts of acid with one part of juice the activity of the ferment is interfered with. The ferment is an albumenoid, but contains much less nitrogen than albumen, and it cannot be replaced by diastase or ptyalin. The quality of the lacquer seems to be dependent upon its richness in urushic acid and poverty in water, the durability of the finished work being due to the oxyurushic acid, which is singularly negative in its reactions, resisting all solvents tried, and being affected only by strong nitric acid. What is known as lacquer poisoning is stated to be due to urushic acid, which gradually disappears; the best antidote for it is sugar of lead.

Mr. J. M. Wood, the Curator of the Botanical Gardens, at Durban, Natal, writes that he has received plants of the true Socotrine aloe, *Aloe Perryi*, direct from Socotra, and that there is a probability that the cultivation of the plant for the sake of the juice will be commenced very shortly in Natal. The specimens sent from Kew to Jamaica appear to have died, according to Mr. D. Morris's report, and it is therefore interesting to learn that there is hope that Socotrine aloes of good quality may again become a commercial article in a few years. Mr. McAlpine, a botanist who has just started for Tasmania, has in view the cultivation of medicinal plants in that island and intends to include among them this aloe. He hopes in the course of a year or two to be able to supply the Antipodes with better samples of henbane, belladonna, etc., than they at present receive from this country.

Mr. T. Darwin, in an article in *Nature* (May 1, p. 7), on the "Absorption of Water by Plants," shows that the rate of absorption is influenced by the dampness or dryness of the air, being more rapid in dry air, owing to the more rapid evaporation from the leaves, and more rapid in sunlight than in shade. He also confirms Baranetzky's statement that a small disturbance, such as a slight shake, by increasing the transpiration from the leaves increases the rate of absorption, while cutting off a twig rapidly diminishes it. A. Sorauer, however, found in some experiments on gourds that the removal of leaves from plants on two occasions did not alter the amount of evaporation in the least; and even when half the leaves were removed from another plant, although a reduction in the amount of evaporation ensued at first, after eleven days the evaporation was equal to that of an untouched plant (*Journ. Chem. Soc.*, xlvi., 627).

The rapid changes of temperature and the dry winds during the last few weeks must have had an injurious effect on the hop gardens exposed to their influence, since according to A. Schwartz (*Journ. Chem. Soc.*, xlvi., 629), these conditions bring about an unhealthy state of the plant under which it readily falls a prey to mildew and aphides, which is not the case with plants sheltered by trees or hills or otherwise protected from the changes of weather, nor with those which being planted late are less liable to be subjected to changes of temperature.

A correspondent, writing from Parkstone, near Poole, Dorset, remarks that the vegetation in that neighbourhood is about three weeks behind owing to the continued east winds. The broom is only now in full blossom, while the elder is just beginning to burst into bloom. In the gardens the bay tree, *Laurus nobilis*, is covered with flowers. The different species of pine, chiefly *Pinus sylvestris* and *P. maritima*, which render the air so fragrant and healthful for many a mile in the neighbourhood of Parkstone, are becoming lit up as it were by the bright green shoots, which contrast pleasantly with the dark tints of the last year's foliage. The abundance of the purple orchis in the meadows suggests that it would be no difficult matter to obtain salep in this country if it were so much valued as in the east.

A number of medicinal plants may be looked for this month. The pretty flowers of the buckbean, *Menyanthes trifoliata*, are in good condition for collection in bogs and marshy ground. The buckthorn may be seen covered with its small green blossoms in hedges in chalky or marly districts. The feathery plumes of the *Pulsatilla* make it recognizable in spots where the flowers might easily be overlooked. The black and white mustard are beginning to give a yellow tint to fields and railway hedge banks, and the red poppy has commenced to give a little brightness to the monotonous green of the cornfields.

At the drug sales during the past month the root of *Ionidium Ipecacuanha* has been offered for sale as the true drug, being classed in the list under the head of ipecacuanha, without any intimation that it differed from the rest of the packages. A quantity of spurious cubebs, which had been sent from this market to America and returned to London, has again been put in the market here and some of it purchased under the belief that it was genuine.

FURTHER NOTE ON WARAS.

BY W. T. THISELTON DYER, M.A., C.M.G., F.R.S.

By an odd coincidence no sooner was my note on this very curious substance printed in the pages of this Journal, by the obliging courtesy of the Editor, than I received a further most interesting communication on the subject from Major F. M. Hunter, Assistant Resident at Aden. It contained a memorandum giving the complete history of the collection of the drug with a further specimen in fruit of the plant producing it, the pods bearing the epidermal glands still undetached. There can be now no sort of doubt that the "waras" plant is really that described by Mr. J. G. Baker, F.R.S., in the 'Flora of Tropical Africa,' as *Flemingia rhodocarpa*.

But my colleague, Professor Oliver, F.R.S., whose kindness is only equalled by his sagacity, has made the curious discovery that a *Flemingia* apparently confined to South India, *F. Grahamiana*, W. and A., is not specifically distinguishable from *F. rhodocarpa*; the pods are in fact clothed with the same peculiar epidermal glands so characteristic of that species. The "waras" plant is therefore really to be found in India after all.

In creating a new species for the "waras" plant, Mr. J. G. Baker pardonably neglected the comparison of the material he was working upon with specimens of the species occurring in so remote and botanically widely severed an area as the southern part of the Indian peninsula.

I trust that room may be found for Major Hunter's memorandum, which I append in its entirety.

NOTES ON "WARS" COLLECTED AT HARRAR IN FEBRUARY AND MARCH, 1884.

"In the neighbourhood of the city 'wars' is not now raised from seed sown artificially, and it is left to nature to propagate the shrub in the surrounding terraced gardens. The plant springs up, among jowari, coffee, etc., in bushes scattered about at intervals of several yards more or less. When sown, as among the Gallas, it is planted before the rains in March. If the soil be fairly good a bush bears in about a year. After the berries [pods] have been plucked the shrub is cut down to within six inches of the ground. It springs up again after rain and bears a second time in about six months, and this process is repeated every second year until the tree dies. Rain destroys the berry [pod] for commercial purposes, it is therefore only gathered in the dry season ending about the middle of March. The bush grows to a maximum height of six feet and it branches close to the ground. The growth is open and the foliage sparse. Each owner has a few acres of land.

"In the middle of February, 1884, the following processes were observed:—

"The leaves [? fruiting shoots] of some plants were plucked and allowed to dry in the sun for three or four days. (The picking is not done carefully and a considerable quantity of the surrounding twigs, etc., is mixed with the berries [pods].) The collected mass was placed on a skin heaped up to about six or eight inches high and was tapped gently with a short stick about half an inch thick. After some time the pods were denuded of their outer covering of red powder which fell through the mass on to the skin. The upper portion of the heap was then cleared away and the residual reddish green powder was placed in a flat woven grass dish with a sloping rim of about an inch high. This receptacle was agitated gently and occasionally tapped with the fingers, the result being the subsidence of the red powder and the rising to the surface of the chaffy refuse, which latter was carefully worked aside to the edge of the dish and then removed by hand. This winnowing was continued until little remained but red powder. (No great pains are even taken to eliminate *all* foreign matter.) A rotl was sold in 1884 for about 13 piastres = 1 rupee 10 as. nearly.

"'Wars' is sent to Arabia, chiefly to Yemen and Hadhramaut, where it is used as a dye, a cosmetic and a specific against cold. In order to use it, a small portion of the powder is placed in one palm and moistened with water, the hands are then rubbed smartly together, producing a lather of a bright gamboge colour, which is applied as required."

SORGHUM SUGAR.*

BY OSCAR HOUCK, PH.G.

The different kinds of sorghum (*Sorghum saccharatum*) now under cultivation in the United States, are varieties and hybrids from two main groups; the one the Chinese sugar cane, or sorgho, or sorghe, from China and India, and the second the African sugar cane, or imphee, from the south of Africa. As varieties of the first group, we have the regular sorghum, Honduras cane, honey top, sprangle top, etc. Of the second group the most important are the Liberian imphees, white African, white mammoth, Iowa red top, and wolf's tail. As hybrids, the early amber is the most common, early orange and a

* From the *American Journal of Pharmacy*, May, 1884.

number of others. These hybrids need, as also their names indicate, a shorter time to attain maturity, and are, therefore, especially adapted for the more northern range, Wisconsin, Minnesota, etc., where the season is rather short; while the countries further south, with a longer season, have the advantage that they can utilize both the early and late varieties, and thus be able to supply the mills for a longer time; besides that they also can utilize the other qualities, desirable in good cane, as saccharine richness, large percentage of juice, and large stalks. A rather sandy loam is said to be the most favourable soil for its cultivation.

The first seeds of the new sugar cane were brought to America in 1854, from France, where they had been imported from China only a few years previous. Not long afterwards also seeds of the African variety found their way over here. And now sorghum is to be found cultivated almost in all parts of the United States, where the climate is favourable to its growth; and it is said that where maize will thrive sorghum also will.

Its principal use has, until lately, been confined to the mere production of syrup, as a very sweet, and, to most persons, agreeable article of this kind may be prepared by means of quite inexpensive machinery. But the production of a cheap, marketable sugar from it has, until the last three years, met with no success. Sugar has, of course, been produced from it long before this, but on account of inferior machinery and limited means it would not pay. It is also said that a fatty substance is contained in the juice of sorghum, which hindered the crystallization of the sugar, and necessitated another process than that used for the common sugar cane. The first sugar reported obtained from sorghum was made by a farmer in Wisconsin (according to Professor Carl Mohr). In 1858 J. S. Levering, a chemist of Philadelphia, received the gold medal from the United States Agricultural Society, as an acknowledgment for his successful and meritorious experiments in sugar making from sorghum (*Amer. Journ. Pharm.*, 1855, p. 182; 1858, p. 105). In spite of the publication of his process no attempt was made to utilize it. Later, through the Commissioner of the Department of Agriculture at Washington, G. W. Le Duc, a great deal was done in order to arouse the interest for it, that new experiments should be undertaken. Steward, a Pennsylvania chemist, also treated the subject, and showed at the Centennial Exhibition, in 1876, samples of sugar which he had obtained by his experiments. With still greater energy Dr. Collier, chemist of the Agricultural Department at Washington, took up the work, and of the results of his thorough investigations he has given a minute account in his several reports, which has thrown much light on the subject.

At the same time Professor Swenson, of the University of Wisconsin, was occupied with investigations of the same kind, and when the United States Government, through the Agricultural Department at Washington, offered a prize of 1200 dollars for the best method of treating sorghum cane it was awarded to him.

Some New York capitalists, after having corresponded with Professor Swenson and secured his service, determined to establish a sugar mill in some portion of the country, where the cane could be grown successfully and cheaply. The Arkansas river valley was decided upon, and in 1882 the mill was built at Hutchinson, Kansas. As an experiment some sugar was successfully made, already late, the same season. Last fall (1883) they made as an average forty barrels of sugar and about two hundred gallons of syrup a day. This was the first undertaking on a large scale, and, as it proved a success, others have followed their example, and many more are likely to follow.

The process used in the above-named mill I have not seen myself, but will give it as it has been described. The cane, having been examined by the chemist and found in the desirable ripe condition (when it contains most saccharose and least glucose), is cut, topped, and hauled to the mill without stripping. Arrived there it is placed on a long endless belt, which acts as an elevator to carry it to the crusher, which consists of huge iron rollers. The cane is passed through this crusher at the rate of twenty-five tons per hour. The juice, as it runs from the rollers, passes into a large tank, from which it is pumped into the defecating room. Here it is run into six defecating pans, capable of holding three tons of juice each. In these are coils of copper tubing, through which steam is passed to heat the juice. To the lukewarm juice is then added milk of lime, until slightly alkaline, in order to neutralize the acids, which are always contained in it, and to coagulate the albuminous matter present. It is then heated as rapidly as possible to the boiling point, and the steam is shut off when the thick scum, which rises to the surface, begins to swell and break. After a few minutes the juice is skimmed, and it is again heated, this time to a quiet ebullition, and again skimmed. This is repeated a few times, and the result is a very clear juice, almost free from sediment. From the defecating room the juice, containing 84 parts of water and 16 parts of sugar, passes to the evaporating pans, where it is boiled down to 54 parts of water and 46 parts of sugar, when it is called "semi-syrup." This passes into a small vacuum pan, and from there into the bone-black filters. These are six in number, and are each cylindrical in shape, 4 feet in diameter and 20 feet high. Here the syrup is decolorized and deodorized, after which it is pumped into the large vacuum pan. This is ovoid in shape, made of boiler iron, and looks like a huge retort. It is 7 feet in diameter, 9 feet high, and will hold more than 1000 gallons. In this the semi-syrup boils at 70° C. under diminished pressure, instead of 110° C. in free air. This is a great advantage, as it is a well-established fact that high heat and much exposure to the air quickens the conversion of saccharose into invert sugar. From the vacuum pan the syrup is put into large iron waggons, which hold about 240 gallons each, and in them is run into the crystallizing room. This room is kept at a temperature of 55° C., and in it the syrup is allowed to stand for several days until it crystallizes. The "melado," as the syrup at this stage is called, is then run into the mixer. This is a long bar with fingers attached, the whole revolving in an iron box. In this the melado is thoroughly mixed and made ready for the last process. From the mixer the melado is run into the centrifugals. These, four in number, are tubular vessels about three feet in length and two feet high, open above and closed below. Each is lined with fine copper sieve, a space of perhaps two or three inches intervening between the sieve and the outer wall of the centrifugal. The centrifugals are set in motion at the rate of 2000 revolutions per minute, and the melado is run into them, falling upon a revolving disk in the centre. From this the melado is thrown with great force against the side of the vessel, striking upon the copper sieve, which is also in rapid revolution. The force of the projection throws the syrup through the sieve, while the crystallized sugar remains behind, whitening the longer it "spins," as the process is called. It is generally allowed to spin about fifteen minutes, after which the raw sugar is taken out and put into barrels, and the process is completed. Each centrifugal is capable of spinning 200 lbs. of sugar in those fifteen minutes. Besides these details, the process has, of course, its secrets, which are also kept as such.

From the above-named factory I obtained a sample of sugar, of which I made an analysis, which shortly will be explained. In appearance the sugar looks very much like the common raw sugar of commerce. But in odour and taste it differs somewhat, as it has retained some of that peculiar sorghum flavour, which is not disagreeable, and in which place in common raw sugar is found a taste and smell of burnt sugar.

In my analysis of the sorghum sugar I found the following constituents:—

Saccharose	92·00 per cent.
Glucose	4·50 per cent.
Moisture	1·50 per cent.
Ash	1·10 per cent.
Impurities	0·90 per cent.
	100·00

The amount of saccharose was ascertained by the use of the Wilde polariscope, which as an average showed 92°. With the same instrument I examined samples of different sugars with the following results (the strength of the solutions was 10 grams of sugar and water sufficient to make 100 c.c.):—

White rock candy polarized	100°
Yellow rock candy polarized	93°
Best granulated sugar polarized	99°
White A sugar polarized	94°
Common raw sugar polarized	84°
Sorghum sugar (4 experiments)	90°, 92°, 93°, 92°

Common raw sugar was also subjected to analysis for comparison:—

Saccharose	84·00 per cent.
Glucose	11·80 per cent.
Moisture	2·50 per cent.
Ash	0·70 per cent.
Impurities	1·00 per cent.
	100·00

The moisture and ash of granulated sugar were also ascertained and found to be respectively 0·55 and 0·44 per cent. This shows in reference to the moisture, that the more glucose contained in the sugar, the more moisture is absorbed. As to the sorghum sugar the comparison is very satisfactory, as it contains 8 per cent. more saccharcse than the common raw sugar, and only 2 per cent. less than the A sugar, which has gone through a refining process. This very satisfactory result is due to the improved machinery, of which the vacuum pan and the centrifugals are the most important, and without which the idea of sugar making, from sorghum, at the present sugar prices, might be given up as almost hopeless. But as it is, sorghum sugar can compete with other sugars, both in price and quality.

CRITICISMS, FROM A CHEMICAL POINT OF VIEW, ON SOME FAVOURITE PRESCRIPTIONS.*

BY HENRY LEFFMANN, M.D.

The few points that I present to the College this evening will include little that is absolutely new, but I think the time will not be entirely wasted, as I know that the prescription list of most of our drug stores will give numerous examples of the violation of chemical principles here mentioned. My attention was called to this topic by my being shown by an apothecary a prescription calling for syr. hypophosph., tinc. ferri chlor., acid. phos. dil., concerning which he said that in the proportions ordered he could never make the mixture up clear. I examined the precipitate, and found in it, as I had expected, a large proportion of the iron and other basic ingredients This is a simple case of incompatibility. Turning the matter over in my mind, it has seemed to me that while some attention is paid to cautioning students as to the general nature of incompatibility, very little or none is given, especially in the shallow chemical teaching of many medical schools, to the properties and qualities of chemical substances in their relations to the animal tissues and the manner of administration. I present here, therefore, a brief consideration of a few well-known remedies.

Under the name of *colourless tincture of iodine* several preparations are used, depending for their popularity on the fact that they do not stain the skin. They are prepared either by the use of ammonia or of sodium sulphite or hyposulphite. They owe their particular property, or rather absence of property, to the neutralization of the iodine, and just to the extent that the iodine is decolorized is it to the same extent deprived of virtue. The free active affinity of the iodine, to which its local action must be due, is destroyed in these preparations, and the destruction is not slow or uncertain, but in two of the methods mentioned it is sufficiently rapid and definite to be made the basis of a method of quantitative analysis. It is certainly difficult to see how any person could go so wide of simple chemical principles as to invent or employ this mixture.

Potassium chlorate, or, as it is still erroneously called by many, chlorate of potash, is a remedy concerning which extraordinary claims have been made, based upon most erroneous notions of its chemical qualities. It is employed in the laboratory as a source of oxygen. Knowledge of this fact has led to its employment as an oxidizing agent in diseases which have been supposed to express deficient oxidation. I have nothing to say here as to the clinical results obtained from potassium chlorate in any disease,—although I believe it is much less in favour than formerly,—but I enter a protest against any advocacy of its usefulness as an oxidizing agent. Under temperatures and conditions such as those which it meets in the human system it is one of the most stable of bodies, does not part with its oxygen or chlorine, and, indeed, will not begin to do so except under very high heat. I have found by actual experiment that ten grains of the salt kept for two hours at a temperature of 100° F. in contact with an artificial gastric juice did not develop oxidizing qualities sufficient to oxidize one-sixtieth of a grain of phosphorus. This experiment is merely confirmatory of what everyday experience with the substance teaches.

Potassium permanganate has been more or less in favour with physicians for a score of years. It is well known as an oxidizing agent; its powers in this respect are well marked. It is as little suitable for internal administration for such purpose as the body just considered, but for an opposite reason. Its chemical properties are developed by almost every substance, and in the doses in which it is given it will be decomposed and rendered inert very shortly after being swallowed. Within a very recent period the salt has come into notice as a remedy for amenorrhœa, and great has been the tribulation of apothecaries. It has been given in pill form, and all the usual excipients have been unavailable. I have made a few tests of the permanganate pills now in the market, and I find with regard to those made by one of the most reliable houses in this city that the permanganate is all decomposed and converted into the insoluble manganese dioxide. The preparations of two other manufacturers made up with some mineral excipient, probably kaolin, were in good condition, but as soon as placed in a mixture of hydrochloric acid and pepsine they begin to decompose into insoluble manganese oxide. These pills vary in strength from one-eighth to one grain. This small quantity of permanganate certainly must soon decompose in the stomach, and the only virtue which it can have is from the manganese itself, and if this is effective common sense would seem to suggest that the result could be best obtained by exhibiting some definite compound of manganese, such as the chloride or sulphate. When we consider the chemical relations of the salt, and almost certain inertness of it in small doses, the gravity with which the learned English therapeutists, who recommend it in amenorrhœa, have discussed the possibility of its producing abortion, becomes almost burlesque. I do not

---

* Read before the College of Physicians of Philadelphia, April 2, 1884. Reprinted from the *Boston Medical and Surgical Journal.*

desire, of course, to impugn the clinical observations that have been recorded on this point, but I feel obliged to say that if the insoluble and variable decomposition products of one-eighth of a grain of potassium permanganate can affect the function of any one organ, then the difference between us and the apostles of the infinitesimal is small indeed.

I cannot dismiss these two compounds, which owe their popularity to mistaken notions of their properties, without saying a word or two as to the exhibition of oxidizing agents. If rational therapeutics or physiological study indicates remedies of the so-called oxidizing class, then it will be found that no better agents are known to us than those which have long been in our hands. In nitric acid, nitro-muriatic acid and chlorinated soda we have substances which are sufficiently stable to resist the organic bodies of the saliva and gastric juice, and are sufficiently active to give oxidizing effects if such (other than local action) can be obtained. I have grave doubts whether the nutritious fluids of the body can be oxidized by any method, but there can be no doubt whatever that such effect cannot be attained by either a body—potassium chlorate—which yields its oxygen only at a red heat, nor by one—permanganate—that decomposes the moment it touches any form of organic matter. Some years since a correspondent in one of our medical journals gravely recommended the use of raspberry syrup to disguise the taste of potassium permanganate. It was, of course, entirely successful, the taste was destroyed, so was the compound.

Caffeine citrate is a remedy much in favour and is a remarkable instance of how much physicians take for granted in the remedies they use. There is no caffeine citrate in the market, and it is doubtful whether any such a salt can be prepared. The commercial preparations are either pure caffeine or variable mixtures of it with citric acid.

The manufacturers in this city each furnish a different article, except in cases in which they buy from a common source; and a house in a neighbouring city furnishes an article which contains no citric acid. Some of the samples are purely bitter in taste while others are distinctly sour. Analyses of some of the commercial salts are recorded in a paper read before the last meeting of the American Pharmaceutical Association, by Dr. G. C. Wheeler. He found the quantities of caffeine varied from 96·5 per cent. to 63·5 per cent.; of citric acid from 63·5 per cent. to 3·5 per cent.; none of these figures correspond with the proportion of a true citrate.

It seems to me that accurate clinical observation cannot be made with a preparation of so uncertain a character; for, as seen by these figures, the proportion of active ingredient may vary 33 per cent., and the lesson that these analyses teach us is that when the effects of caffeine are wanted they are best obtained by the use of the pure alkaloid and not by a pretended and uncertain compound of it.

PSEUDOMORPHINE.*

BY O. HESSE.

In his first communication on this alkaloid, which he obtained from opium, the author stated his belief that it was identical with the oxymorphine of Schützenberger, and that its formula was $C_{17}H_{19}NO_4$. Brockmann and Polstorff (Abstr., 1880, 408) contended that this oxymorphine had the constitution $(C_{17}H_{18}NO_3)_2$, and based their assumption principally on the fact that nitric oxide was evolved in its production from a solution of morphine hydrochloride and silver nitrite, whereas the formula $C_{17}H_{19}NO_4$ would require an evolution of nitrous oxide. The author now shows that if an aqueous solution of morphine hydrochloride is mixed in molecular proportions with a solution of potassium nitrite, and the whole heated for some time at 60°, crystals of oxymorphine are formed and a gas evolved which does not turn red in contact with the air, and is consequently not nitric oxide. The formation is evidently due to the decomposition of morphine nitrite,

$$2C_{17}H_{19}NO_3,HNO_2 = 2C_{17}H_{19}NO_4 + N_2O + H_2O,$$

and the author points out that an evolution of nitric oxide, when silver nitrite is used, might also be explained by the equation—

$$4C_{17}H_{19}NO_3,HNO_3 = 4C_{17}H_{19}NO_4 + N_2 + N_2O_2 + 2H_2O.$$

The author now finds that the body $C_{17}H_{19}NO_4$ is a hydrate of the real base, and that the formula for oxymorphine is, therefore, $C_{17}H_{17}NO_3$. The hydrate loses its water at 130°, but the base is so very hygroscopic that it is only by taking special precautions that rehydration can be prevented. The less crystalline the specimen in question, the more marked is its hygroscopic character. The alkaloid is best purified by solution in ammonia, from which it crystallizes in colourless crusts containing $1\frac{1}{2}H_2O$, which it loses at 130°. The *hydrochloride*, $C_{17}H_{17}NO_3,HCl$, crystallizes in scales containing, under varying conditions, respectively 1, 2, 3 and 4 mols. H_2O. A *basic hydrochloride*, $(C_{17}H_{17}NO_3)_2,HCl + 6H_2O$, is obtained in microscopic crystals from a hot neutral acetic solution on the addition of sodium chloride: from a cold solution, the basic salt crystallizes with $8H_2O$. With platinum chloride both the neutral and basic salts yield a yellow flocculent platinochloride

$$(C_{17}H_{17}NO_3)_2,H_2PtCl_6.$$

The *hydriodide*, $C_{17}H_{17}NO_3,HI + H_2O$, loses its water when exposed to the air: the *chromate*,

$$(C_{17}H_{17}NO_3)_2,H_2Cr_2O_7 + 6H_2O,$$

loses $4H_2O$ at 80°: the sulphate crystallizes with $6H_2O$, and effloresces slightly in dry air, but when crystallized from boiling water it is stable: the *oxalate* yields shining scales, with $8H_2O$: the *acid tartrate*,

$$C_{17}H_{17}NO_3,C_4H_6O_6 + 6H_2O,$$

crystallizes in needles or prisms. Heated for two hours at 120° with acetic anhydride, pseudomorphine yields *diacetylpseudomorphine*, $C_{17}H_{15}(C_2H_3O_2)_2NO_3$. It crystallizes from ether in concentrically grouped flat prisms, containing $4H_2O$, which it loses in the desiccator. It is moderately soluble in ether and chloroform, very soluble in alcohol, in which it yields a strongly alkaline solution. It contracts at 250°, but does not melt until 276°. It gives no coloration with ferric chloride. With hydrochloric acid it forms a salt crystallizing in quadratic tables, easily soluble in water. With platinum chloride this salt yields a pale yellow flocculent *platinochloride*,

$$[C_{17}H_{15}(C_2H_3O)_2NO_3]_2,H_2PtCl_6 + 6H_2O.$$

The di-acetyl compound is easily reconverted into the original base by heating it with alcoholic potash. It is clear, therefore, that the hydroxyl-groups of morphine are still present in pseudomorphine. The author was unable to obtain a methyl compound by the action of potassium hydroxide and methyl iodide. He, however, obtained pseudomorphine methyl-hydroxide,

$$C_{17}H_{17}NO_3,MeOH.$$

The author also believes pseudomorphine to be identical with the substance which E. L. Meyer (*Ber.*, iv., 121) obtained by the action of moderately concentrated sulphuric acid on a nitro-compound which he had obtained by passing a strong current of nitrous anhydride into water in which morphine was suspended.

THE COMPOSITION OF OIL OF GAULTHERIA.*

BY HARLAN P. PETTIGREW, PH.G.

The author gives a brief account of the investigations made by Professor Procter on the oil of sweet birch (*Amer. Jour. Phar.*, xv., p. 241), and of the information

* From the *American Journal of Pharmacy*, May, 1884.

furnished by G. W. Kennedy (*Ibid.*, 1882, p. 49), regarding its manufacture on a large scale and its sale in place of oil of gaultheria; and he refers to his chemical investigation of this oil (*Ibid.*, 1883, p. 385), which showed it to be methyl salicylate. The first experiments on the chemical composition were made by Procter (*Ibid.*, xiv., 211); afterwards a fuller chemical investigation was made by Cahours (*Ibid.*, xv., 241, from *Jour. de Phar. et de Chim.*, May, 1843). To the latter is generally attributed the statement that this oil contains 10 per cent. of terpene; but in the French journal named no mention is made of a terpene, and the presence even of methyl alcohol was not conclusively proved, as the following abstract from that paper shows:—"On treating this oil with a solution of potassa of 45° B., to which fragments of that alkali were added, and submitting the mixture to a regulated heat and distilling, a distillate was obtained in the receiver which, after being treated several times with lime, furnished a liquid more volatile than water, and burning with a pale blue flame." The original papers on "Salicylic Compounds," published by Cahours in *Annales de Chimie et de Physique* and in *Comptes Rendus*, could not be consulted.

Two different specimens of oil of gaultheria were examined by the writer; one was obtained by Professor Maisch, from Messrs. Underhill, Concord, N. H., and was distilled by them: the other was obtained directly from a distiller in Ellenville, N. Y., and both were guaranteed to be absolutely pure. These oils, when received, had already acquired a very slight reddish tinge, but upon redistillation were obtained as bright, colourless and quite highly refractive liquids, having the sp. gr. 1·17, both corresponding in this respect with the sp. gr. of oil of wintergreen as determined by Procter.

The oils were treated separately, 190 grams being operated upon in each case. The plan followed in the investigation of this oil was the same as that adopted in the analysis of the oil of birch (*Amer. Jour. Phar.*, 1883, p. 385), namely, saponification by treatment with a concentrated solution of potassium hydrate and boiling over a sand-bath in a flask fitted with an inverted condenser. After complete decomposition of the oil, the contents of the flask were submitted to distillation upon a sand-bath until the residue remaining in the flask was nearly dry. The distillate thus obtained presented a milky appearance, and globules of a yellowish oily substance were seen floating upon the surface. This is one striking difference between this oil and the oil of birch, as the corresponding distillate obtained from the latter was perfectly clear and transparent. The distillate was then agitated in the flask in which it was collected, with several successive portions of ether, and the ethereal solutions were carefully separated from the aqueous liquid, and the ether recovered by distillation upon a water-bath. The residue remaining in the flask then consisted (besides a few drops of water) of a yellowish oily substance, which was lighter than water and possessed a very strong peculiar odour entirely different from that of the oil of birch or wintergreen. The terpene was then weighed without any attempt being made to purify it, as the amount was small. This determination was only approximate, yet the amount of terpene found amounted to but 0·3 per cent. of the weight of the oil.

The aqueous liquid which remained after extracting the terpene by agitation with ether, and which contained the methyl alcohol, was perfectly clear and transparent, and the alcohol, which was obtained by repeated distillation of the liquid from a water-bath, collecting only the lighter portions which passed over first, and further rectifying these by distilling from caustic lime, possessed the same odour, and was of the same sp. gr. and boiling point as methyl alcohol.

The salicylic acid was obtained by making an aqueous solution of the salicylate of potassium, which remained in the flask after the first distillation, and decomposing this by the addition of a slight excess of hydrochloric acid, the chloride of potassium formed remaining in solution, while the salicylic acid formed as a dense white precipitate which, after washing with water and drying, was obtained pure by crystallizing from hot petroleum benzin.

Both specimens of oil examined yielded about the same amount of terpene, but as a portion of one of them was accidently lost, no attempt was made to weigh the small amount remaining.

These results show that oil of gaultheria, sp. gr. 1·17, does not contain 10 per cent. of a terpene; for, if it did, the specific gravity of the oil would necessarily be very much lower than that of the oil of birch, in which the absence of a terpene has been conclusively proved.

Whether the oil of gaultheria which has been distilled in the spring or summer contains more of the terpene than that distilled in the fall, is not known; but from results obtained by experiments made upon a specimen which was distilled in the spring, it seems that there is a difference, as this oil was found to have a sp. gr. of but 1·0318, and the absence of alcohol was shown upon application of several of the tests for that substance.

After referring to Mr. Kennedy's paper read before the American Pharmaceutical Association (see *Amer. Jour. Phar.*, 1883, p. 533; also 1883, p. 85), the writer continues:—According to information upon this subject obtained from a distiller of oil of gaultheria, the oil, which is seen floating in small globules upon the water, will, if allowed to stand twenty-four hours, all collect together into large drops, and settle to the bottom of the containing vessel. This alone shows that this oil cannot consist of a hydrocarbon, but to decide the question conclusively, a small amount of water, which was taken from the receiver just as it came over from the still, was agitated with several successive portions of ether, the ethereal solutions, being carefully separated from the water, were evaporated, whereby only a very small amount of oil was obtained, which did not possess any odour of the terpene, and which consisted only of the pure oil of gaultheria. This shows that the terpene does not become separated in the process of distillation.

The results of these investigations may be briefly summarized as follows:—

I. Oil of birch is not identical with oil of gaultheria, in that it consists entirely of salicylate of methyl, and contains no terpene.

II. Oil of gaultheria, sp. gr. 1·17, does not contain 10 per cent., but only a very small amount, of terpene, to the presence of which is due the slight difference in odour and specific gravity between the two oils.

THE ALKALOIDS OF COPTIS TRIFOLIA.*

BY JOHN J. SCHULTZ.

To find the proportion of alkaloids in *Coptis trifolia*' 5 pounds of carefully selected coptis, in moderately coarse powder, were moistened with officinal alcohol and packed firmly in a properly prepared cylindrical percolator. Officinal alcohol was then added in successive portions of 2 gallons each. The last portion was acidulated with 4 ounces of acetic acid. After each addition, maceration was conducted for twenty-four hours, and percolation was continued until the percolate finally passed almost colourless and devoid of any bitter taste.

Five gallons and 5 pints of percolate of a yellowish brown colour and decidedly bitter taste were obtained. The dregs after having been removed from the percolator and dried at a temperature of 110° F., weigh 4 pounds and 8 ounces, showing a loss of 8 ounces.

* From the *American Journal of Pharmacy*, May, 1884. These experiments were carried on in the laboratory of Professor J. U. Lloyd, upon authentic specimens furnished by him. We take this opportunity to thank him for the attention shown us.

To 4½ pints of this percolate, representing 8 ounces of drug, an excess of sulphuric acid was added and the mixture set aside in a cool place.

To 1 pint and 2 ounces of percolate, representing 2 ounces of drug, an excess of hydrochloric acid was added and the mixture set aside with the foregoing.

After standing forty-eight hours a precipitate had formed in each, that of the sulphuric acid being light yellow, while that of the hydrochloric acid was yellowish brown.

The supernatant liquids in each case were bitter and retained a decided yellow colour, characteristic of berberine, showing that the precipitation of the berberine had been incomplete.

Two pints and 4 ounces of the original percolate, representing 4 ounces of drug, were then subjected to distillation, until the residue was of a syrupy consistence. The retort was then rinsed with 8 ounces of water, the result placed in an evaporating dish, and the last traces of alcohol vaporized. A dark greenish fixed oil and a lighter coloured resin began to separate as the alcohol evaporated, and these were completely precipitated by allowing the liquid to stand in a cool place for twenty-four hours. The contents of the dish were then thoroughly agitated with water and filtered. The filtrate was now evaporated to a syrupy consistence and 8 ounces of alcohol added. This was divided into two equal portions, and one was strongly acidulated with sulphuric, the other with hydrochloric acid, and both set aside in a cool place.

After standing twenty-four hours, the portion acidulated with sulphuric acid had formed a considerable amount of a brownish-yellow precipitate, but the supernatant liquid was still bitter and retained its yellow colour. The portion acidulated with hydrochloric acid showed only a slight cloudiness, and did not precipitate even after standing for two weeks.

The foregoing processes are the ones usually employed for the separation of berberine, and neither, in these instances, gave a satisfactory result.

Through the courtesy of Professor J. U. Lloyd, we were enabled next to employ his scheme for the determination of berberine, as stated in the manuscript of his work upon 'Drugs and Medicines of North America,' and which is based upon the insolubility of picrate of berberine in most menstruums.

The first step was to separate the second alkaloid, discovered by Mr. E. Z. Gross, as follows:—Of the remainder of the percolate, 4 gallons and 1 pint, representing 4 pounds of drug, were subjected to distillation, and the oil and resin separated in the manner heretofore described. To the resulting filtrate, officinal water of ammonia was added until slightly in excess. This produced a dark brown flocculent precipitate, which was collected on a filter and thoroughly washed with water. The filtrate, after having been slightly acidulated with sulphuric acid, and allowed to stand for several hours, was brought to an alkaline reaction by the addition of water of ammonia, when a second precipitation took place similar in appearance to the first. This and the foregoing precipitate after having been mixed and dried spontaneously, were treated with successive portions of chloroform. The chloroform was then distilled, and the residue exhausted with dilute sulphuric acid. The resulting solution when filtered and made alkaline by addition of ammonia water, gave a precipitate which, when dried spontaneously, weighed 3·42 grains.

A portion of this precipitate when dissolved in water acidulated with acetic acid, gave precipitates with the following reagents for alkaloids:—Platinic chloride, molybdate of ammonium, solution of iodine in iodide of potassium, and test solution of iodide of mercury and potassium.

A chloroformic solution of the remainder of this precipitate when evaporated on a slide formed microscopic crystals, but the quantity obtained was too small to admit of further investigation. (This was the second alkaloid as found by Mr. Gross.)

To a portion of the filtrate, from the foregoing precipitates, solution of carbonate of sodium was added without producing any precipitate, and it was positively shown that there was no more of this second alkaloid present.

To the entire filtrate and washings thus obtained from the second alkaloid, and which were of alkaline reaction, a solution of carbazotate of ammonium was now added. This produced a bulky yellow precipitate of carbazotate of berberine, which, when collected on a filter and dried spontaneously, weighed 292·8 grains, corresponding to 228·03 grains of sulphate of berberine.

In order to test the filtrate for any remaining alkaloids, a portion was evaporated nearly to dryness on a water-bath, and agitated successively with ether, chloroform, benzol and carbon disulphide.

The several solutions were evaporated, the residue dissolved in water and portions of it separately tested with test solution of iodide of mercury and potassium, molybdate of ammonium, and chloride of platinum, without producing any precipitate, thus showing the previous complete separation of all the alkaloids.

Recapitulation.—The foregoing experiments show, that *Coptis trifolia* yields to U.S.P. officinal alcohol, slightly acidulated with acetic acid, 10 per cent. of its weight of extractive matter. That it contains two alkaloids, as previously shown by the investigations of Mr. E. Z. Gross (*Am. Journ. Pharm.*, 1873). That the berberine of *Coptis trifolia* is only partially separated by the processes usually employed for the determination of berberine. That it contains of berberine an amount equivalent to 0·8 per cent. of sulphate of berberine, or 57 grains of sulphate of berberine to the avoirdupois pound. That the amount of the second alkaloid is very small, 0·012 per cent., or only 0·855 grain to the avoirdupois pound having been obtained.

PINKOS TUBERS.

Under the name "Pinkos-knollen," a very hard red woody substance has lately been introduced into the Vienna market, probably from Australia, which is found to be almost as valuable for turning purposes as ivory. Dr. Franz von Höhnel has subjected this substance to careful examination, and has determined, from the following characters, that it is the product of a coniferous tree belonging to the family Araucarieæ:—1. The absence of true vessels. 2. The absence of resin passages. 3. The extremely thin-walled medullary rays, consisting of a single row of cells, comparatively large, and placed in bulgings of the tracheids. 4. The remarkable pits which indicate the tracheids on the borders of the medullary rays. 5. The large bordered pits of the tracheids, which meet from opposite sides, usually placed in two rows, and then nearly polygonal. 6. The sclerenchymatous pith, from 4 to 5 millimetres wide. The so-called "tubers" are turnip-shaped, 15–40 centimetres long and 7–16 broad: broad and apparently broken off at one end, running out into a point at the other end. The transverse section shows a sclerenchymatous pith, 4–5 millimetres wide, surrounded by a number of very narrow annual rings, the older of which are concentric, the outer ones strongly excentric. They are usually covered by rotten wood and soil, and are probably gigantic knots which have fallen out of decaying and mouldering trunks in the primeval forest. Of the genera of Araucarieæ they must be derived from either *Araucaria* or *Dammara*, and very probably from *Araucaria Bidwillii*, the "bunya-bunya pine," a native of New South Wales.

The Pharmaceutical Journal.

SATURDAY, MAY 31, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTRAR-GENERAL'S RETURNS AS TO DEATHS BY POISONING.

WHITSUNTIDE is at hand, and Parliament has adjourned over the last ordinary recess in the session; but up to the present time the Government has given no sign with respect to the Poisons Bill which it has promised to introduce into the House of Lords. The introduction cannot, however, be much longer delayed, if the promise is to be fulfilled at all, so that the issue of another annual return of the Registrar-General, including among other things the statistics as to the deaths by poison that occurred in England in the year 1882, is opportune as furnishing information that will no doubt be quoted should the question reach the stage of legislative discussion this year. It is to be regretted, however, that the information which these statistics convey is not more precise, since they are lacking in just those details which would be most valuable at the present time. But probably the form in which a large proportion of the returns as to deaths by poisoning are at present received by the Registrar-General would render futile any attempt at making the classification much more definite.

The total number of deaths returned as due to poisoning during the year 1882 was 599, or 30 in excess of the previous year. Of these 246 deaths of males and 120 of females are referred to the division "accident and negligence," 117 males and 111 females to "suicides," and 5 to "murders." As the deaths from all causes in England in 1882 numbered 516,654, those that were attributed to poison therefore amounted to 1 in 863 of the whole. But it requires very little consideration to see that a very large number of these "poisoning" cases were such as would not be affected by any provisions likely to be included in a Poisons Bill. In the first place in 228 of them poisons were used by persons intent upon destroying their own lives, a class out of whose reach it is almost as hopeless to attempt to keep poisons as it would be razors, ropes, and rivers. Then out of the 366 deaths by poisoning referred to "accident and negligence" it is probable that not a few would be more fitly dealt with in a Noxious Trades Bill, as, for instance, the majority of the 78 deaths that are attributed to lead poisoning. It is of graver import in connection with the expected legislation that of the residue of the 366 deaths, after making deductions on account of sanitary shortcomings, no less than 115 are referred to mishaps with substances that are more or less narcotic. It will also be of interest to note respecting the substances which in the Draft Pharmacy Bill it is proposed to include in the schedule of "poisonous articles," that in this same class of deaths through "accident and negligence," 8 are referred to sulphuric acid, 4 to nitric acid, 7 to hydrochloric acid, and 15 to carbolic acid. It would be hardly worth while, however, to go through the details *seriatim*; but it may help to the formation of a judgment of the relative importance of the Registrar-General's statistics if we bring the principal facts together in a tabular form.

The second reading of the Medical Acts Amendment Bill in the House of Commons stands as the fifth order of the day on Thursday next. But notice of motion that it be read that day six months has been given by no less than six different members.

* * *

The New Brunswick Legislature has recently passed a Pharmacy Act for that division of the Dominion of Canada. Under its provisions the New Brunswick Pharmaceutical Association is incorporated, and its provisions are described as being very similar to those in the Ontario Pharmacy Act, published before on p. 892. It appears, however, to differ in one important respect, in that although there is a schedule of poisons that can only be sold legally by qualified persons, there is no provision as to the registration of the sale of any of them. We hope shortly to receive a copy of the text, and will then refer to the Act more fully.

* * *

The City of Boston boasts of an "Inspector of Vinegar," whose last annual report to the city council has just come to hand. It appears that the standard for vinegar adopted by the inspector is an acidity equivalent to the presence of not less than 5 per cent. by weight of absolute acetic acid, and for cider vinegar, which is the variety most favoured in Boston, a fixed residue at 212° F. of not less than 1·5 per cent. of "cider vinegar solids." The report states that the means of determining whether any vinegar conforms to these required limits are simple and may be obtained from any dealer in chemical apparatus or from one of the apothecaries, and then goes on to describe how the acidity may be ascertained by means of a volumetric solution of soda and an alcoholic solution of phenol phthalein, and the residue by evaporation. But unhappily for the peace of mind of the amateur analyst who may aspire to test his own purchases it is afterwards hinted that the acidity may have a mineral origin and that of cider vinegar should give the reactions for malic acid.

In a recent report on the commerce of the port of Loanda, Mr. Consul Cohen says the natives of Angola smoke, besides tobacco, the leaves of a plant which they call "liamba." These leaves are alleged to produce highly stupefying and narcotic effects exceeding those following the use of opium, confirmed smokers, among whom are included many Europeans, becoming idiotic and useless in a few years. Mr. Cohen says he is not aware that any chemical analysis of the plant has yet been made.

According to an official statement the number of candidates who in the year 1882-3 became qualified pharmacists in the German empire was 315, of whom 139 qualified in Prussia, 59 in Bavaria, 52 in Saxony, 12 in Würtemberg, 14 in Baden, 5 in Hesse, 6 in Mecklenburg, 11 in the grand duchy of Saxony, 9 in Brunswick and 8 in Elsass-Lothringen. This shows a falling off as compared with the previous year for the second year in succession, whilst during the same time there has been a considerable increase in the number of medical men who have become qualified.

* * *

In a communication to the *Medical Tribune*, Dr. Kunze states that while passing through a large New York drug store in the third week of January, he was surprised to notice two open barrels filled with fresh roots of *Convallaria Majalis.* Upon closer examination and inquiry he found that these roots were from forced hothouse plants, from which the flowering stem and leaves had been cut off for the flower market, and that this practice of turning the exhausted roots to account was not uncommon. Under these circumstances Dr. Kunze thinks it is not surprising that physicians fail to obtain the results expected from the use of preparations of convallaria, and he suggests that the old astrologers, in requiring that a plant intended for medicinal use should be gathered under certain planetary influences, had the advantage in practice, since the gathering of the plant in the best possible condition was probably thus secured.

At the last meeting of the Philadelphia College of Pharmacy it was resolved that the museum, laboratories and hall of the college should be open daily for the inspection and use of visitors during the meetings of the British Association and the American Pharmaceutical Association in September.

* * *

A correspondent of the *Ceylon Observer*, in giving an account of a visit to Japan, says that the Japanese tradesmen are among the greatest adepts at adulteration in the whole world. Even in drugs they have begun to imitate foreign articles with complete success, save that the English labels occasionally baffle them. Thus in shops in the native quarter of Yokohama boxes labelled "Hallaway's Pills" are sold at ten sen (4*d.* to 5*d.*) a box, as the manufacture of Professor Holloway. A foreign resident mentioned that his servant having been sent to a foreign druggist for some magnesia went to a native store, in order to get his squeeze, and brought back what appeared to be roughly ground chalk.

It is announced that the first open surgical scholarship of the Society of Apothecaries of London has been awarded to Mr. Sidney Plowman, St. Thomas's Hospital.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The ordinary monthly meeting was held in the Society's Rooms, on Wednesday evening, May 14, Mr. Preston, the President, in the chair.

The Secretary, Mr. Newsholme, having read the minutes of the previous meeting, placed upon the table a sample of ginger mixed with nux vomica beans.

Mr. Newsholme said the sample was supposed to be African ginger. It weighed 4 ounces; out of this weight he had picked $\frac{3}{4}$ ounce of nux vomica beans or about 20 per cent. of the whole (7 lbs. contained $1\frac{1}{2}$ lb. nux vomica).

A paper was read by Mr. George Ellinor, entitled "A Short Description of some Cinchona Barks."

A discussion ensued, which was joined in by most present, and at the conclusion, a hearty vote of thanks was awarded Mr. Ellinor for his paper.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 15. Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—W. T. Burgess, E. J. Caley, R. D. Courtney, M. H. Foye, W. F. Grace, Baron Ferdinand von Mueller, H. Rogers, A. J. Watts.

Dr. J. H. GLADSTONE then read a paper—

On Refraction Equivalents of Organic Compounds.—In this paper the author gives the results of observations which have been made from time to time since 1870. These results are contained in three tables giving the refractive indices, etc., of over one hundred and forty substances. Table I. contains the refractive indices of the liquid bodies from observations of the lines A, D, and H. Table II. gives a list of the solvents employed and the percentage amount of substance dissolved. Table III. gives the specific refraction, dispersion, and refraction equivalent of all the substances as deduced from observations and the theoretical refraction equivalent calculated from the values of the respective elements given below. The specific refraction is the refractive index for A *minus* 1 divided by the specific gravity or $\frac{\mu A - 1}{d}$. The specific dispersion is $\frac{\mu H - 1}{d} - \frac{\mu A - 1}{d}$ or which is the same thing $\frac{\mu H - \mu A}{d}$. The refraction equivalent is $\frac{\mu A - 1}{d}$ × the atomic weight. The following are the values of the elements:—Carbon saturated, 5·0; carbon in C_nH_n, 5·95; carbon, double linked, 6·1; hydrogen, 1·3; oxygen, joined by single bonds, 2·8; oxygen, joined by a double bond, 3·4; nitrogen, 4·1; nitrogen in bases, NO_2, etc., 5·1; chlorine, 9·9; bromine, 15·3; iodine, 24·5; sulphur, joined by single bonds, 14·1; sulphur, joined by a double bond, 16·0 The author has not included in the tables the refraction equivalent calculated for the theoretical limit of the spectrum because of the increasing uncertainty as to the position of such a limit. The author then gives the data by which the refraction equivalents of the above elements are calculated and in conclusion draws special attention to two points, the phenomena of dispersion and the bearing of these optical phenomena on our views as to the structure of organic compounds.

Dr. Armstrong asked if Dr. Gladstone had used benzene prepared from benzoic acid, as Meyer had shown that all benzenes prepared from coal tar contained thiophene, and thus the refraction equivalent of carbon in benzene might be affected. He ventured to protest against the use of the terms double linked, double bonds, etc., which he trusted would soon become obsolete; it would be better to speak of carbon in the ethylenic condition, etc. He also thought it would be most important, if possible, to determine the specific dispersion as well as the specific refraction.

Professor McLeod suggested that some use might be made of Captain Abney's photographic results and that it would be better to determine the refraction of liquids at a fixed distance from their melting point rather than from their boiling point.

Mr. TURNER then read a paper—

On the Estimation of Silicon in Iron and Steel.—The author has estimated the silicon in samples of iron and steel containing from 0·06 to 22 per cent. of silica by the various methods usually employed, and comes to the conclusion that the method suggested by Watts is most generally applicable, and gives, when slightly modified, accurate results The method (*Journ. Chem. Soc.*, Abstr., xlii., 1134) consists in passing dry chlorine free from air over the iron borings at a low red heat. The chloride of iron volatilizes and is condensed in the colder portion of the combustion tube, whilst the silicon chloride passes on and is decomposed by passing it through water, which on evaporation yields the silica. Any slag and the silicon contained in it remain behind in the porcelain boat unattacked. The improvement suggested by the author is the use of a Will and Varrentrapp's bulb to contain the water by which the silicon chloride is decomposed; the loss of the silica which used to adhere to the delivery tube and the beaker is thus avoided, as the bulb can be dried and weighed after the experiment. A table accompanies the paper, giving the results obtained by six different methods and six samples of iron and steel.

Dr. TILDEN then read a—

Note on the Melting Points and their Relation to the Solubility of Hydrated Salts.—In a paper read before the Royal Society in June, the author, in conjunction with Mr. Shenstone, proved that a relation existed between the melting points of anhydrous salts and their solubility in water above 100°. In the present paper the author shows that a similar relation holds between the points of fusion of hydrated salts and their solubility below these temperatures. He has determined the melting points of many salts and gives the method by which the determinations were made. The temperature at which incipient fusion occurs is in many cases that at which the graphic curve representing the solubility suddenly turns upwards. In isomorphous salts containing the same amount of water of crystallization the solubility and the fusibility stand in the same order at all temperatures below the point of fusion. The most fusible being the most soluble. The author is greatly in want of experimental data as to solubilities and melting points in order to extend the subject further.

A Memoir Detailing some Minor Researches on the Action of Ferrous Sulphate on Plant Life. By Dr. A. B. GRIFFITHS.—The author finds that 0·15 per cent. of ferrous sulphate added to a solution of various salts aids, whilst 0·2 per cent. is fatal to the development of mustard seeds, cabbage plants, and some microscopic water plants.

Note on Ferric Sulphocyanate. By A. J. SHILTON.—The author finds that if a drop of dilute ferric chloride be allowed to fall into a solution of potassium sulphocyanide the red colour at first formed is completely discharged. Also that a liquid containing enough ferric sulphocyanate to render it almost opaque is completely decolorized if boiled with an excess of hydrochloric acid. These effects are readily explained by the fact that the sulphocyanide is a powerful reducing agent.

The Society then adjourned to June 5.

SOCIETY OF ARTS.

Fermentation and Distillation.

In the second Cantor lecture upon "Fermentation and Distillation," on the 19th inst., Professor Hartley mentioned that soluble can be easily distinguished from organized ferments by their solubility and indefinite infusibility in water. He also gave the results of analyses made of papayin by Wurtz, of pancreatin by Law, and of albuminous peptone by Henniger, which showed that all of them contained about 16·5 per cent. of nitrogen, 52·5 per cent. of carbon, and 7·25 per cent. of hydrogen. Though the action of these ferments is impeded by borax, organic substances known as antiseptics produce no effect. They combine energetically with mineral matters, especially phosphates, and though there is no apparent change during the fermenting action, their power is gradually lessened. Diastase may be obtained as a white powder from malt by extraction with water, heating the liquor and filtering, and then precipitating with absolute alcohol; it is found to amount to only about 1 part in 500 parts of malt. One-seventh of the diastase in raw malt, however, is sufficient to convert the starch into sugar, though sometimes one-fourth may be required, owing to a too high temperature, above 112° F., having been reached during the mashing process. If a saccharine solution of it be slightly warmed a turbidity and incipient ebullition ensues, afterwards resulting in a very energetic evolution of carbonic acid gas; a small quantity of yeast added to the solution quickens this action. If a solution of grape sugar be exposed to the air for some time, the same results are obtained. This action is due to the growth of small bodies of an oval shape, known as yeast, which multiply at an enormous rate. These bodies were shown in 1835 by Schwann to be living organisms consisting of a cell, in which is contained an albuminous fluid. In further experiments it was found that yeast and other germs are at all times present in the air, but that these germs must come in actual contact with the saccharine matter to cause decomposition. Various methods for the preservation of saccharine solutions from this decomposing action were described. If a quantity be boiled and the mouth of the vessel be plugged with cotton-wool after the expulsion of all the air, the wool acts as a kind of filter, preventing the ingress of the germs with the air upon cooling; a still more effective mode consists in constructing the mouth of the vessel with a series of sharp bends, in which the germs in the air entering are deposited or else killed by the steam issuing when boiled. The lecturer then showed the difference between badly fed and well-nurtured yeast. The germs of the former have a shrivelled, pitted appearance, and a very distinct outline. If these germs be placed in sweet wort, which contains a quantity of mineral, especially phosphate of potash, and nitrogenous food, they swell out and the outline gradually becomes more indistinct; it is further observed that the germs commence to bud, the buds growing rapidly and soon becoming detached. In the alcoholic ferment two distinct varieties of the yeast plant (*Saccharomyces cerevisiæ*) are found, whilst a third has been claimed to have been distinguished. Bottom yeast, which is found in the lower part of the fermenting vat, develops at a temperature of 43° to 50° F., and never rises to the surface, even if the temperature be raised to 68° F. It buds less rapidly than the higher yeast, and is principally used for lager beer. The yeast found near the surface of the vat consists of larger and fatter cells, forming at a temperature of from 60° to 68° F., though quite inactive at a lower temperature. Professor Hartley then enumerated the principal conditions for a successful fermentation. The saccharine solution must be of a suitable strength and contain sufficient phosphates and nitrogenous food; it is also necessary that the yeast plant should be in a healthy state. Attention must be further paid to the due proportion of yeast to sugar, as an excess of sugar precipitates the albuminous matter, whilst a want of it induces an irregular fermentation, which allows the introduction of other ferments producing other than alcoholic products. The fermentation of cane sugar occupies twice as long a period as that of grape sugar, as the cane sugar has to be inverted into glucose before being split up by yeast. The alcoholic ferment resolves the saccharose into glucose as dextrose or levulose, which is again resolved into alcohol, carbonic acid gas, glycerine and succinic acid; 100 parts of saccharose yield 105·36 parts of glucose, which split up into 51 parts of alcohol, 48·5 parts of carbonic acid gas, 3·16 parts of glycerine, ·67 part of succinic acid, and 1 part of cellulose, etc. Professor Hartley gave as the result of a yeast ash examined by himself, that it consisted nearly entirely of phosphate of potash with a slight trace of soluble silica; it is therefore apparent that without potash the yeast plant will not grow, the substitution of soda being of no use, though sometimes a magnesium salt is found in the ash. Beans and other legumes are sometimes steamed and added to the fermenting liquid, as they are rich in the needful nitrogenous food. The danger of the use of unhealthy yeast is the probable contamination with lactic or other ferments. The bacterium of the lactic ferment is the *B. subtilis*, resolving the glucose into lactic acid. Those of the butyric ferments are the *B. amylobacter* and *B. ethylicus*, resolving the glycerine into ethylic alcohol; *B. butyricus*, resolving the glycerine into butyric alcohol, butyric and lactic acids, and propylglycol; and the *B. Termo*, causing oxidation of organic matters generally. As all these organisms are smaller than the yeast plant it requires a microscopic power of not less than 700 diameters to examine them. Several methods are used for the purification of the yeast. The plant is grown in a 10 per cent. solution of sugar, in consequence of which the lower organisms are starved out from want of nutritious food, after which the yeast is transferred to sweet wort, where it speedily flourishes. In other methods the use of small quantities of tartaric, carbonic or salicylic acids have been advised. Yeast has also been taken from various sources and mixed, thus affording more chance of obtaining a pure yeast; but with all these precautions bacteria are sometimes introduced subsequently with the addition of the finings.

The concluding lecture of this course consisted principally of an explanation of the different modes of distillation, though some interesting remarks were made concerning the natural production of alcohol. The original yeast plant, possibly derived from the grape or hop vine, has been lost in cultivation. But besides this there are many other ferments that produce alcohol, those of rhubarb and dates especially causing a very rapid decomposition when heated. The iodine test for alcohol, producing crystals of iodoform, was described as sufficiently delicate to detect one part of alcohol in one million parts of water; by the use of this test it has been shown that organic decay leads to a continual production of alcohol in the earth, though it is far less in a sandy barren soil than in one containing much organic matter. Traces of alcohol have been found in nearly all water except that collected from some deep springs; rain water indeed has been found to contain 1 gram weight of alcohol in a cubic metre of the water. These results have been confirmed by experiments made by Captain Abney with the spectrum method. Mr. Hartley then explained the principle of the common still, and drew attention to the great loss of heat in the cooling method, which had first been successfully avoided on the manufacturing scale by the arrangement introduced by Laugier. His plan consisted in utilizing the heat abstracted during the cooling of the alcohol for the purpose of raising the temperature of the liquid to be distilled. The parts of the apparatus consisted of two stills, one being used as a rectifier, a dephlegmator, and a condenser. A more modified form of this apparatus, designed by Coffey, is at present in use in English spirit manufactories for the distillation of fermented worts. In both these methods advantage is taken of the low boiling point and diminished latent heat of alcohol as compared with water to separate the alcohol, the strength being regulated by the rapidity of the distillation. It is further found that a comparatively stronger alcohol is obtained by the distillation of a wash containing a low percentage of alcohol. Thus if the wash consist of 90 per cent. alcohol, with a boiling point of 173° F., the distillate will contain 92 per cent. of alcohol; but if the wash only has 60 per cent. alcohol, the boiling point rises to 178° F, whilst the distillate contains 87 per cent. of alcohol or a comparative increase of 27 per cent. With a wash of 20 per cent. alcohol a distillate containing 71 per cent. or an increase of 51 per cent. is obtained. The well-known improvement in flavour consequent upon the keeping of whisky, etc., Mr. Hartley considered due to the conversion of some of the amylic compounds into ethers. In a homologous series of alcohols he mentioned methylic, ethylic, propylic, butylic, amylic, caproic, œnanthic, caprylic, rutic, lauric, cetylic, cerylic and melissic alcohols. He also pointed out the existence of the base C_6 in the composition of the aromatic benzene derivatives, consisting of benzine, cymene, benzoic, cinnamic and salicylic aldehydes, vanillin, anethol, thymol and eugenol. He then referred to the manner in which the barley-malt is dried as imparting a distinctive flavour to the spirit obtained from it, this being especally the case when dried over peat fires; the lecturer considered the flavour due to the formation of certain compounds which remain in the malt. In conclusion he gave the result of an analysis of a sample of Highland malt whisky. About 200 c.c. was taken and divided into eight equal fractions by distillation. The first four, distilled at 78° C., consisted of almost entirely pure ethylic alcohol, though a faint trace of butylic alcohol was noticed in the third fraction; the fifth and sixth fractions, distilled at 78° to 95° C., consisted principally of amylic compounds, whilst the remaining two fractions were chiefly water with a faint trace of amylic alcohol.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, May 15, Mr. H. G. Greenish, Vice-President, in the chair.

The following paper was read on—

The Botany and Materia Medica of Linseed.

BY E. H. EARLE.

The plant, known from the value of its products in manufactures and the arts as *Linum usitatissimum*, is an upright annual having a height of from one to two feet. The stem is smooth and green, and the leaves are linear lanceolate, alternate, and sessile. The calyx consists of five sepals which are ovate and acute, and have membranous margins. The corolla consists of five petals which are of much larger size than the sepals. They are somewhat crenated and are caducous. These petals are of a conspicuous purplish blue colour. Both stamens and styles are five in number. The fruit is a capsule, which dehisces septicidally; the carpels being divided from each other, and these again partially divide down the partition between each pair of seeds.

The native country of the flax plant is unknown, but central Asia has been mentioned as the probable source.

The plant is reared in this country in Lincolnshire, Cambridge, Suffolk, Devon, and Somersetshire. The seeds obtained from the two latter counties are held in highest esteem. In India the flax plant has been under cultivation for centuries for the seeds, whereas in Europe the fibre of the plant was more developed, as linen and not oil was desired.

Experiments have lately been made in India with Dutch and American seed, with a view to cultivating a good flax-yielding plant, but they have not as yet been very successful. This is said to be owing to insufficient moisture in the soil. The seeds are sown in the autumn. India also imports much European grown seed for the extraction of the oil, which possesses more satisfactory drying properties than that obtained from native grown seed. At least such is stated to be the case.

Flax being the more important of the products of this plant, I will allude to it first.

Flax has been known from the earliest ages. It constituted a field crop at the period when the Israelites were in Egypt, and the fibres were used for the manufacture of garments. Herodotus mentions this fabric as constituting articles of clothing amongst the Egyptians, upon whose monuments and tombs the processes which the fibre underwent for economic purposes are depicted with great accuracy. The clothes in which the mummies are wrapped are found to consist of linen, but of a very coarse texture. It was also used for filtering wine through, and a very rough or strong quality formed sails for boats, according to classical writers.

The Romans seemed to prefer wool to linen in the way of clothing. The emperor Alexander Severus is reported to have been the first Roman who had the courage to wear a linen shirt. After the fall of the Roman Empire flax-weaving was lost sight of until the tenth century, when it was started at Ypres in Flanders, and was from that time carried on in various parts of the Continent with varying success. I believe the celebrated Bayeux tapestry is worked on linen.

The seeds from which the flax plant is to be reared should be plump, heavy, and shining; and should be freed from impurities by sifting.

The soil answering best for its cultivation is a dry loam, and in good flax-growing soils silica is found to the amount of 60 per cent., or, in some cases, 80 per cent. Flax has always been notorious for exhausting in a high degree the soil from which it is raised. In the Georgics Virgil speaks of it as "scorching the fields." This was owing in a great measure to the cultivators not understanding the rotation of crops. Thus many districts are barren in Sicily and Asia Minor—once the granary of Rome—Spain, and the Campania, which were historically fruitful.

Irish grown flax is considered the best for the manufacture of linen, and there the crops are rotated so as to allow of an interval of about six years before again using the soil for flax. The first year grass is grown; in the second year oats; in the third year potatoes or turnips; in the fourth year wheat; in the fifth year flax, clover, or beans. In this way the soil suffers no harm.

In order to obtain a superior fibre for linen manufacture the plant is gathered before it reaches maturity, which is indicated by the partial change of the green stem to yellow, and of the green capsule to brown.

The stem consists essentially of a woody interior, and externally of the fibre needed for flax.

The plant is gathered and dragged through a rough comb, which separates the capsules. This is known as "rippling" it. It is next "retted," which operation consists in steeping it in soft water for about a fortnight, in order to dissolve out the gummy and resinous matters holding the woody and fibrous portions together. Ponds have to be dug out for the purpose of steeping the flax, as the plant renders the water so offensive that cattle drinking at a river or stream in which the operation had been conducted would be poisoned. In the reign of King Henry VIII. an Act was passed forbidding the pollution of river water by such means.

In Sweden the plant is boiled in sea water, together with lime and birchwood ashes, and finally washed with soap. This operation ended, it is "grassed" or laid out for sun-bleaching, being turned once or twice in order that all parts may experience the same influence. This occupies about a fortnight. It is then tied in sheaves or bundles and sun dried. It is often broken or "scutched" before being sent into the market. This process consists in beating with mallets or flails until the adhering wooden portion is well broken up. This is now chiefly done by machinery. It undergoes in the mills many processes which are too intricate to be followed out in a paper of this nature, beside involving some technical education. After being "combed" or "heckled" in the mill in order to separate the fibres, flax presents long glistening silver gray or yellowish fibres resembling silk when viewed from a short distance. The fibres broken off short in combing constitute tow.

Flax is also imported from the Baltic ports, Holland and Belgium.

Scraped linen constitutes lint. There has been some discussion from time to time as to the superiority of lint over cotton in bandages. Cotton is more irritating, and this is said to be due to the cells, of which it is composed, being flat and having sharp edges, or by these flat cells twisting when wetted, in both cases proving uncomfortable to the patient. Flax cells, however, are cylindrical, and thus, having no sharp edges, are superior for dressings.

The seeds now come under our notice. They are small, brown and glistening; oval in shape and having sharp edges. They are official, being used for the infusion of linseed. They are used for food in some parts of Russia and Abyssinia.

The seed coats contain a mucilage, according to some writers, which exists in the *growing* plant as *starch*. The nucleus contains much fixed oil (about one-third the weight of the seed). It is when first expressed of a pale colour, but darkens on keeping. It consists chiefly of glycerides, together with fatty acids—notably, linoleic—to which the drying properties are due.

The seeds are obtained from St. Petersburg, Riga, Libau and other Baltic ports both in Russia and Germany, the Black Sea ports, Bombay, Calcutta, Italy, New York and La Plata in South America. The Baltic supplies the greatest amount and the La Plata seeds go chiefly to the Continent.

Linseed meal is officially directed to be obtained by powdering the cake from which the oil has been expressed. It is used as a poultice, which is often stated to have irritating instead of soothing effects. This may be due to the admixture of cruciferous seeds, such as rape and mustard. As the irritation was supposed to arise from the natural oil of the linseed becoming rancid, the meal is directed to be obtained—as stated before—from the *cake* and not from the seeds. Olive oil is directed to be added when a poultice is required, in order to replace the natural oil, which to say the least is an inconvenient arrangement.

Taking now the expression of the oil from the seeds as actually carried on:—The seeds are stored by means of an elevator at the top of the warehouse, and by means of a long wooden tube, a stream of this seed is poured into a large wooden box, which allows a regulated amount to pass in a continual stream between two almost solid steel rollers about 18 inches in diameter, and on emerging from between these the seed falls upon a sloping iron ledge which directs the steam between two more rollers, and so on, until by a course shifting from one side to the other, the seeds emerge finely ground, and constituting a true linseed meal.

The temperature of the room is about 90°, so that a more plentiful supply of oil should be yielded.

Machinery now carries the meal into a large tub-like arrangement known as the "kettle." A workman below waits with iron trays upon which are coarse cloths. These trays are about a yard long and a foot wide.

These trays are placed below the "kettle," from which, by means of a trap, a requisite amount of meal is deposited upon the cloth-covered tray. The meal is pressed just sufficiently to cause it to adhere together and it is then covered at the top by the ends of the cloth before mentioned, and the tray is then placed in a press by another workman, who accumulates a pile of about a dozen in the press in about ten minutes.

At the bottom of this pile of trays is a solid steel slab which now ascends and presses the cakes against the top of the press. The oil flows very freely into tanks below, which have only one small hole for the oil to run out of. This prevents a too rapid current, which would carry mucilage and other matter along with the oil, which runs through a series of tanks, always depositing until it reaches the large storage tanks, from which casks are filled for sale or export.

The press being loosened again, the trays are removed and the cake, now apparently quite dry, is divested of the cloth which was used to allow of the cake being more easily removed from the trays, and the edges neatly bevelled by means of a sharp knife running in a groove, which cuts the cake to the required shape and size.

The portions of cake trimmed off are ground up and worked over again.

These cakes weigh about 12 pounds and contain mucilage, phosphates and nitrogenous matter and about 4 per cent. of oil, which renders them of great service in cattle feeding.

The seeds I saw worked were Calcutta seeds and appeared remarkably free from admixture. Thirty-three per cent. of oil was extracted and 4 per cent. left in the cake, so these seeds yielded very good results.

Linseed oil may be divided into four kinds, raw, refined, boiled and artist's.

Raw oil is obtained in the manner just described.

Refined oil is raw oil allowed to stand for weeks or even months, to allow impurities to settle and then is treated with litharge or acetate of lead either when hot or cold. It is also sometimes heated with sulphate of zinc or alum, which is said to hasten the deposit of impurities. The lead is often separated with oil of vitriol and this bleaches the oil and also converts any lead into sulphate, which might, when mixed with paint as white lead, be converted otherwise into yellow oxide when exposed to air.

Boiled oil. Here the oil is boiled for about five hours, and then dryers are gradually added in the proportion of 5 pounds to a ton of oil. The whole is then boiled for an hour. After this the oil is left by some manufacturers until a pellicle forms, when the oil is then run off or ladled out. Some manufacturers allow it to stand for weeks until all the dryers have settled and the oil is clear and bright. The sediment and scum are used in putty. It is tested by dipping sized paper into the oil and seeing if a varnish is formed, on drying, over the *whole* of the paper. If only the bottom of the paper is varnished whilst the top remains greasy the oil is insufficiently boiled. The drying into a resin or varnish is seen to be due to the absorption from the air by oxygen, by spreading the oil over zinc plates and weighing. When a varnish is formed the weight of the oil is found to have increased by nearly one half.

Boiling oil was almost a traditional arrangement for promoting its drying; but black oxide of manganese and red lead were added with the idea of giving to the oil at a high temperature that amount of oxygen requisite to aid its commencement in absorbing oxygen from the air. The black oxide is said to part with oxygen, which it again absorbs on being stirred to the surface, over which a current of air is passing. Borate of manganese is also used. The pans in which the boiling takes place are of copper or iron, with an iron jacket, and are heated by steam. They have a dome cover, from which two fans or stirrers are arranged to stir up the oil. From the dome the irritating vapours of acrolein are conducted into bottles of water.

Lastly comes artist's oil. There are several kinds, which are made to suit private forms, and consist chiefly of heating the oil with acetate of lead and litharge, and bleaching with ferrous sulphate or by exposure to sunlight.

This paper was followed by one on—

The Chemistry of Linseed.

BY EDWARD CULLINAN, JUN.

The chemistry connected with linseed and its products is not only very interesting, but has received some very important technical applications.

Composition of the Seeds.—The testa contains an abundant secretion of mucilage; the cotyledons, a fixed oil. The average composition of linseed, as analysed by Dr. T. Anderson, shows the following results:—

Albuminous substances	24·24	parts in 100.
Oil	34·00	
Gum, sugar and cellulose	30·73	
Ash	3·33	
Water	7·50	

A more complete analysis of the seeds by Meyer gave the following results:—

Fat oil	11·265	parts in 100.
Wax	·146	
Acrid soft resin	2·488	
Resinous colouring matter	·550	
Yellow extractive and tannin	1·917	
Sweet extractive, malic acid and salts	10·884	
Gum	6·154	
Nitrogenous mucilage, acetic acid and salts	15·120	
Starch	1·480	
Albumen	2·782	
Gluten	2·932	
Husk	44·382	

The seeds are principally cultivated for the oil, but linseed cake, *i.e.*, the marc left after the expression of the oil, is also a valuable substance for feeding cattle. According to Voelcker's analysis* it contains:—

Oil	10·90	parts in 100.
Albuminous substances	24·56	
Mucilage, starch and digestible fibre	31·97	
Woody fibre	11·47	
Ash	6·20	
Moisture	14·90	

The proximate substances contained in the seeds may be conveniently divided into four: (1) mucilage, (2) albumen, (3) sugar, (4) fixed oil. Of these only Nos. 1 and 4 will be considered now.

Mucilage.—This is a universal constituent of plants, although found in some under different modifications. According to Thomé, linseed mucilage is formed by the conversion of the epidermal cells into mucilage by the excessive thickening of the cell wall; the innermost layers under the influence of water swell to an extraordinary extent and burst the outer layers, emerging from them as a transparent mucilage. It may, therefore, be considered as a product of the transformation of the cell-wall. It is contained in the testa of the seeds. It may be obtained from them by boiling with water (by which means it will be obtained in thick threads) or by shaking the seeds with acidulated water, filtering, heating to coagulate albumen, concentrating and precipitating with alcohol. It is less transparent and brittle than ordinary gum, insoluble in cold water or alcohol. In a dry state it contains about 10 per cent. of mineral substances, but if freed from these and dried at 110° C. it yields a formula corresponding to $C_{12}H_{20}O_{10}$ (similar to althæa mucilage. With boiling nitric acid it gives crystals of mucic acid. The mineral constituents contained in it are chiefly phosphates of potassium, magnesium, and calcium. The seeds yield about 15 per cent. of mucilage. It is a most useful material for luting stoppers and other such joints in glass works.

Fixed Oil.—This is obtained from the seeds with or without the aid of heat. Preliminary to pressing the seeds are crushed to a fine meal. For the finest quality of cold drawn oil this meal is enclosed in horse-hair envelopes and pressed either by means of wedges, in a screw press, or in a special form of hydraulic press. The cake left may then be submitted to heat and again pressed. Practically cold drawn oil is seldom prepared, but after the seeds have been ground they are roasted (to destroy mucilage) and the oil expressed. The yield of oil is from 23 to 33 per cent. According to Mr. E. Woolsey, the quantity of oil varies according to the weight, quality, and kind of seed used, and his experiments show that the quantity of oil extracted is from thirteen to twenty gallons per quarter, and that the seed known in commerce as "Best Odessa" yields the most oil. Ladurean states that Russian linseed grown in France becomes valueless after the second generation, and the ash is found to lose more than half its phosphates (*Chem. Soc. Journ.*, 1880). Elaborate descriptions of the machinery employed for extracting the oil may be found in Ure's 'Dictionary of Arts.'

When expressed without heat, linseed oil presents very little colour and no unpleasant taste, but the commercial oils are usually dark yellow with a peculiar taste and odour. According to Sassure's analyses it contains—

Carbon	75·17	parts in 100.
Hydrogen	10·98	
Oxygen	13·85	

corresponding to the formula $C_{15}H_{23}O_2$. Chemically it is a glyceride of linoleic acid. By saponification it yields glycerin and fatty acids, oleic, palmitic (Schuler), myristic and linoleic. If boiled for some time it loses weight, becomes thick, and dries up readily to a sold transparent varnish, called linoxyn ($C_{32}H_{54}O_{11}$). Heated to 323° C. it takes fire and leaves tar and charcoal, but if interrupted by closing the vessel, a brown turpentine body will be left, similar to bird-lime. Bromine and chlorine will combine with the oil at a temperature of 50° to 80° C., yielding dark brown liquids, known as brominated and chlorinated linseed oils, and having the formulæ represented by $C_{15}Br_2H_{26}O_2$ and $C_{15}H_{26}Cl_2O_2$. With H_2SO_4 (specific gravity 1·478) it is turned green; with strong sulphuric acid it is turned yellow-brown, coagulated and at last formed into a tough ropy mass, which, mixed with water or spirit, has been used for precipitating gelatin under the name of "Hatchett's artificial tannin." Exposed to the air it absorbs oxygen and forms a resinous mass called oxylinoleic acid ($C_{16}H_{23}O_5$), and this takes place much more rapidly if the oil be heated. In combining with oxygen it evolves much heat and has been known to cause the inflammation of cotton waste. It is soluble in 5 parts of boiling water, 32 parts of alcohol, and 1·6 parts of ether, and it will dissolve sulphur, selenium, arsenic and phosphorus. Sulphur dissolved in four times its weight of oil forms a brown viscid mass, known as "fatty balsam of sulphur." A solution (6 in 1) is contained in the non-official formulary of the Dutch Society for the Advancement of Pharmacy (*New Remedies*, 1882). Boiled with dilute nitric acid it becomes thick and hardens in the air to a substance possessing the property of softening in warm water and resembling caoutchouc.

The oil obtained from linseed belongs to that class known as "drying," and these are of sufficient importance to warrant our consideration.

Drying Oils.—This is a division of fixed oils which, when exposed to air, absorb oxygen and ultimately become converted into a yellowish supple varnish. They contain a glyceride different from non-drying oils and yield by saponification, linoleic or some similar acid. It is probable that they contain a glyceride of linoleic acid, stearin and palmatin, by the varying proportions of which their differences are determined. They are not solidified by treatment with nitrous acid and mercuric nitrate, and they are distinctly heavier than non-drying oils.

* *Journal Royal Agricultural Society*, 2nd series, vol. xvi., p. 659.

The following is a list of the principal drying oils, together with specific gravities and solidifying points :—

Cress seed oil . .	Lepidum sativum .	·924—15° C.
Deadly nightshade	Atropa Belladonna.	·925 – 27° C
Gourd seed . .	Cucurbita Pepo . .	·9231 – 15° C.
Grape seed . .	Vitis vinifera . .	·9202 – 11° C.
Hemp seed . .	Cannabis sativa . .	·93075 – 27·5° C.
Linseed . . .	Linum usitatissimum	·935 – 20° C.
Poppy seed . .	Papaver somniferum	·927 – 18° C.
Sunflower seed .	Heleanthus annuus.	·925 – 16° C.
Scotch fir . . .	Pinus sylvestris . .	·931 – 30° C.
Tobacco seed . .	Nicotiana tabacum.	·923 – 15° C.
Walnut seed . .	Juglans regia . .	·928 – 18° C.

Those in common use are linseed and nut, hemp, and poppy seed oils.

Linoleic Acid.—This acid belongs to the $C_nH_{2n-4}O_2$ group. Its formula is $C_{16}H_{28}O_2$ or $C_{15}H_{27}COOH$. It occurs in linseed and poppy seed oils, and probably in all drying oils. It may be prepared from linseed oil by saponifying, purifying the soap by salting out, dissolving in excess of water, and then throwing down by excess of calcium chloride. The precipitate, which is linoleate of calcium, is washed, pressed, and digested in ether, which dissolves it. The ethereal solution is decomposed by hydrochloric acid, linoleic acid being formed, which is soluble in the ether. The ether is then distilled at a low temperature in a stream of hydrogen, leaving impure linoleic acid. It may be purified by dissolving in alcohol, precipitating as a barium salt with ammonium chloride and barium chloride, washing, pressing and again dissolving in ether. This is then decomposed with hydrochloric acid, the ethereal layer drawn off, redistilled in a current of hydrogen and finally dried in a vacuum over sulphuric acid.

Mulder estimates it approximately by saponifying, dissolving the mixed fatty acids in alcohol, carefully evaporating, crystallizing out the palmitic and myristic acids and converting into lead salts. The oleate and linoleate of lead may then be extracted with ether, and the linoleate separated by repeated evaporation in air and resolution in ether (*Amer. Journ. Pharm.*, xl., 249).

Linoleic acid is a yellowish limpid liquid, insoluble in water, soluble in ether and alcohol, having a weak acid reaction. On exposure to air it oxidizes to a thick viscid mass. Its salts are very easily oxidized. Nitrous acid and mercuric nitrate do not form elaidic acid with it. The formula attributed to it is doubtful. If correct the acid is isomeric with palmitolic and homologous with sorbic ($C_6H_8O_2$) and stearolic ($C_{18}H_{32}O_2$) acids.

Uses of Linseed Oil.—The principal use of the oil is in the preparation of oil paints and varnishes, but it is also used in the preparation of linoleum, oil cloths, printing inks, and gummed silks. For painting and varnishing it is used either as raw or boiled oil. Boiled oil is prepared by boiling the raw oil for two hours, ladling off scum, and then adding a certain proportion of "dryers." The substances used for this purpose are kept as trade secrets, but they are generally composed of equal parts of minium and litharge, or a mixture of these with other substances, such as manganese dioxide, lead acetate. Messrs. E. Barruel and Jean recommend that the resinification be effected with manganese borate. After the admixture of "dryers" the oil is again boiled for some hours, and after cooling stored in tanks so that the uncombined dryers may settle to the bottom. The theory of boiling has been differently explained and is not understood. Liebig suggested that by the process the mucilage and foreign matters were removed; Chevreul, that the chemicals oxidize the oil and thereby induce a more rapid absorption from the air.

Adulterations of Linseed Oil.—The substances used for this purpose are very numerous. Not alone are the seeds mixed with other kinds before expression, but the oil itself is frequently sophisticated. Nearly all but the very best samples are impure. The principal adulterations are cotton, rape, poppy, and hemp seed oils and rosin, mineral and fish oils. These adulterations are very difficult to detect, although the following tests are useful in determining them:—

(1) *Density.*—The true oil varies from ·932 to ·937; boiled oil from ·940 to ·941. Mineral and seed oils are lighter, rosin oil is heavier. All the samples of commercial oils that I have tested have been lighter, and have varied from ·930 to ·931

(2) *Solidifying Point* of pure oil is – 27° C., but samples containing other seed oils freeze at a higher temperature.

(3) *Elaiden Test.*—This consists in treating the oils with nitric acid and copper, or nitrous acid and mercuric nitrate. The non-drying oils are converted into a more or less solid mass of "elaiden." By this means almond, olive, rape and castor seed oils may be detected. I exhibit a number of different "elaidens" obtained from different oils.

(4) *By passing Chlorine into the Oil.*—If fish oils be present the colour will change from brown to black. Fish oils may also be detected by the action of nitric acid. Ten grams of the oil suspected to contain fish oil may be treated with 3 grams of nitric acid, stirred and left to separate. Pure oil becomes green and then a dirty yellow green, whereas a mixed oil becomes dark brown and even black.

(5) *Flashing Point.*—A mixture of hydrocarbons with linseed oil always diminishes the flashing point. The true flashing point of linseed is 283° C., whereas Mason has found that samples of oil mixed with hydrocarbons present a flashing point as low as 128° C.

(6) *Behaviour with H_2SO_4.*—When 50 c.c. are mixed with 10 of strong sulphuric acid, a rise of temperature from 14° to 134° C. takes place, whereas with sunflower, poppy, olive, and almond, the rise in temperature is between 14° to 90° C. (Dragendoff's 'Plant Analysis,' translated by Greenish).

The principal adulterations of boiled oil are rosin and rosin oil. Allen states that the latter may be detected by titrating with alcohol and alkali, and extracting with ether. By evaporating to dryness the rosin may be extracted and recognized by taste and smell, and even in favourable circumstances presenting the physical characters of rosin.

Adulterations of Linseed Cake.—According to Holderfleiss, Ranuard and Corenwinder (*Journ. Chem. Soc.*, 1882–3) it is largely adulterated with rape cake, hemp and colza seeds, and other seeds belonging to the Cruciferæ. Rape and colza seeds may be detected by Maibho's test. Boil with potassium hydroxide, filter and test with lead acetate paper. A black colour indicates sulphur present in cruciferous seeds. The presence of these seeds, as stated by Greenish and others, is highly injurious in their use in medicine.

Much of my information has been derived from the works of Allen, Gmelin, Watts and others, and also from original papers by various authors, most of which have been acknowledged when referred to. I am also indebted to and desire to thank Mr. Dunstan for laboratory assistance, Mr. Earle for samples, and Mr. Walker for practical details.

The two papers gave rise to a discussion in which the Chairman, Secretary, Messrs. Dymond, Lowe and Short took part.

Votes of thanks were passed to Mr. Earle and Mr. Cullinan.

The Reporter on Analytical Chemistry, Mr. C. Thompson, then read a report on "The Separation of Cobalt and Nickel."

A discussion followed in which the Chairman, Secretary and others took part.

Miscellaneous business having been proceeded to, Mr. Thompson introduced the subject of the estimation of carbolic acid, which had formed the substance of a previous report by him, and stated that the method then described by him (titration with bromine water) had been found to give too high results, probably from the precipitation of cresol and higher homologues by bromine water.

After some remarks on the subject by the Secretary, the meeting adjourned.

Parliamentary and Law Proceedings.

Suspected Death by Poisoning.

Some time ago an inquest was held at Ilfracombe on the death of Mr. James Shipway, a retired tradesman, who died under peculiar circumstances. He lived in the Torres, with two female servants as attendants. He was a cheerful man and of robust health for his age, but in March last he frequently was attacked with sickness. Dr. Foquett was called in, but Mr. Shipway died during one of the attacks. A *post-mortem* was made and the doctors could not account for death. They found the inward parts much inflamed and containing fluid of a dark bloody character, and their suspicion was that death resulted from irritant poison. The inquest was adjourned in order that an analysis might be made.

The inquiry was resumed on Monday, the 12th inst., at the Town Hall, before Mr. J. F. Brougham, Coroner.

The first witness called was Dr. Stevenson, of Guy's Hospital, and analyst to the Home Office. He stated that the dark fluid he found in the stomach was blood, but as the bowels had been cut open he was unable to determine the source of the blood, that was to say, whether it had been effused before or after death. Traces of antimony were found in the liver, too small to permit of accurate estimation; also a quantity of bismuth, an appreciable amount. The groats from which the deceased had been eating gruel were free from poison, but the lozenges stamped "Crowther," which the deceased had been eating, contained preparations of morphia and antimony. The medicines deceased had been taking were harmless; but the bismuth, a sample of which he had received from Dr. Foquett, contained a very minute trace of arsenic. The quantity of this, however, was too small to produce any appreciable effect, otherwise the article was pure. The only articles submitted to him which appeared to have any bearing on the case were the lozenges. The use of those accounted for the presence of the only noxious substance found in the body, namely, antimony, and the minuteness of the quantity of the metal in the viscera pointed to its administration in a small dose or doses, such as contained in the lozenges. The use of an excessive number of those lozenges within a limited period would cause nausea, feebleness of the heart's action, and possibly sickness and slight irritation of the bowels. One ounce of the lozenges per day would certainly be an excessive number. He had read and considered the evidence of Dr. Foquett and Dr. Fox, and having regard to that and to the facts of his analysis, he was of opinion that the death of the deceased was due to natural causes. He had known cases where the symptoms had been similar to those of Mr. Shipway, simulating irritant poisoning, and hemorrhage in the bowels, found after death where the cause was ascertained to be natural. There was nothing in the case to warrant the suspicion that deceased was poisoned by anyone or by himself, but the medical men were quite justified in refusing to give a certificate before an inquest was held and an analysis made.

Dr. Foquett was then called and subjected to an examination. He refused to say his suspicions were removed, contenting himself with remarking that as Dr. Stevenson had not discovered any irritant poison he supposed it was not there. Cases were on record where people had died from poison and yet no traces of poison had been found after death. In answer as to whether he thought the fluid in the stomach was blood, he said he did not think so.

The Coroner briefly summed up, recommending a verdict of death from natural causes.

Mr. Thorne also addressed and jury, and pointed out that as the housekeeper was known to be benefited under the will of deceased she had occupied an acutely painful position for many weeks past, and he asked the jury to express their sympathy with her.

This the Jury did, and said they were unanimous in their opinion that death was the result of natural causes. They were also glad to hear Dr. Stevenson say that the medical men were justified in refusing to give a certificate.

Review.

Elements of Pharmacy, Materia Medica and Therapeutics. Second Edition. By William Whitla, M.D.*

This work, which has reached a second edition, has undergone careful revision, though perfect accuracy has not in all cases been obtained. The sections on non-official remedies and chemical reactions have been re-written and extended. The manual has been arranged chiefly for the benefit of medical students, which may account for the detailed explanation of processes connected with dispensing, which will appear unnecessarily elaborate to those who are practically engaged in pharmacy.

The tabular method of conveying information will be found useful if only as a hint to students of the advantage of preparing similar tables for themselves.

The two most useful portions of the book are the chapters devoted to therapeutics and non-official remedies; the medical recipes which illustrate the former continue to render the treatment of this section clear and definite. No one can afford to neglect the study of the long list of substances which, though not officially recommended, are extensively prescribed.

So great attention is at this moment devoted to practical work, both in medicine and pharmacy, that we have separate treatises issuing from the press on several of the subjects included in this volume; but as a ready and comprehensive reference, Dr. Whitla's pages may be consulted with much economy of time. That probably was one chief object contemplated by the author in the compilation of this volume. Essentially it is an excellent guide to students preparing themselves for an examination, and may lay claim to concise teaching and well classified arrangement.

The author insists on the value to the medical profession of a practical acquaintance with the art of pharmacy, and regrets that a more intimate knowledge of this art is not cultivated by the student of medicine.

We may insist, on our side, on the value to the pharmacist of a more intimate acquaintance with the leading principles of therapeutics and posology.

The practice of pharmacy can never be adopted by the medical profession without unduly interfering with those onerous duties which demand their unremitting care; but a knowledge of the principles on which the art is based would instruct both the surgeon and the physician how to prescribe accurately and intelligently; while a general insight into pharmacy would infinitely widen the choice of remedies.

The practice of medicine can never be adopted by the pharmacist, for he does not possess the requisite qualifications. But to know the leading principles on which the science is based would deduct one chance of error, and would infinitely widen the area of his research.

Both parties would be in a truer relative position, and be better able to render mutual companionship and aid.

Obituary.

Notice has been received of the death of the following:—

On the 1st of May, Mr. Joseph Malpas Oakey, Pharmaceutical Chemist, Preston. Aged 70 years. Mr. Oakey was a Founder of the Pharmaceutical Society.

On the 5th of May, Mr. Edmund Thornton Butler, Chemist and Druggist, King's Cross Road, London. Aged 52 years.

On the 14th of May, Mr. Frederic South Morris, Chemist and Druggist, Birmingham. Aged 57 years.

On the 18th of May, Mr. Hugh Davies Hughes Chemist and Druggist, Walworth, London. Aged 52 years.

BOOKS RECEIVED.

Grundriss der Pharmakognosie. By F. A. Flückiger. Berlin: R. Gaertner. 1884. From the Publishers.

New York and Brooklyn Formulary of Unofficial Preparations. By a Joint Committee of Delegates. New York. 1884. From the Committee.

The Extra Pharmacopœia of Unofficial Drugs and Chemical and Pharmaceutical Preparations. By W. Martindale and W. W. Westcott. Third Edition. London: H. K. Lewis. 1884. From the Authors.

Correspondence.

Dr. Redwood's Liquid Extract of Cinchona.

Sir,—Immediately after the Evening Meeting of April 2, I commenced some experiments with a bark by Dr. Redwood's process, and had obtained results which seemed of interest, when, in consequence of domestic bereavement, I was obliged for a time to discontinue them.

In the meanwhile Mr. Cownley published results which closely coincided with those I had obtained; he, however, as might be expected, has made a much more complete analysis of the various alkaloids than I have attempted. My apology for publishing this note rests in the fact that in the letter which Professor Redwood published in the Journal for May 10, he states "that the results obtained by Mr. Cownley are explicable only by assuming that the sample of bark he operated on differed very much from any I have employed." The bark that has been used in the following experiments cannot be objected to on these grounds, for by De Vrij's method it gave 4·625 per cent. of alkaloid, of which 0·72 per cent. was quinia and 2·932 cinchonidia.

In the same letter the Professor adds, "I attach much importance to the degree of comminution of the bark in treating it by this process," and he raises a doubt as to whether Mr. Cownley used a sufficiently fine powder. Now in the private proof of the paper which was issued before the meeting was held "Red Cinchona Bark in No. 60 powder" was directed to be used. At the meeting the Professor stated that with a powder of this degree of fineness percolation was sluggish and that he had since substituted bark in No. 40 powder with equally good results. On the day following the meeting I started, therefore, with bark of this degree of fineness. When the Journal appeared, however, the number of the powder was again altered, and the bark was ordered to be used in "No. 50 powder." It would thus appear that uncertainty as to the proper degree of comminution existed in the author's own mind.

1. *Preparation of the Dry Extract.*

With the exception that Dr. Redwood's verbal instructions, as given at the meeting, were followed, so that the bark used was in No. 40 powder, the process, as it afterwards appeared in the Journal, was strictly adhered to. The percolate no longer gave a precipitate with liquor sodæ when 11 pints had been collected. Upon diluting the concentrated liquid with water, the matter thrown out was extremely difficult to separate; it refused to settle after standing for several hours, and blocked the pores of the filter upon attempted filtration. After the lapse of fifty hours the whole had been filtered and washed. Again the process of drying on glass occupied much time, and when dry the extract adhered most tenaciously to the surface; if the glasses were removed for a few minutes from the hot chamber it was almost impossible to remove it with a knife. By scraping the warm glasses in the chamber fair scales were obtained. Considerable loss was entailed by this difficulty and only 3 ounces of dry scaly extract were obtained.

2. *Estimation of Alkaloid in the Dry Extract.*

Twenty grains of the extract dissolved in 1 fluid ounce of water treated with 3 drachms of liquor sodæ gave 0·069 grams or 1·062 grains of alkaloid equivalent to 5·31 per cent.

Ten grams of the extract treated by a modification of De Vrij's process gave 0·926 grams of alkaloid or 9·26 per cent.

3. *Amount of Alkaloid left in the Marc.*

One hundred grams of the dried marc gave by De Vrij's process 2·23 per cent. of alkaloid, showing that a little more than half the alkaloid present had been extracted by the dilute acid.

4. *Hygroscopic Property of the Dry Extract.*

To test the hygroscopic property of the dry extract obtained from this bark 2·492 grams of it was left exexposed in an open dish for forty-eight hours, at the expiration of which the weight was 3·608 grams, showing an increase of 48·3 per cent.

5. *The Fluid Extract.*

Taking 9·26 per cent. as the alkaloidal strength of the dry extract the fluid extract was prepared according to the directions. The result was highly satisfactory, the product being an elegant aromatic extract of full aroma and bitterness, but which precipitated slightly upon dilution with water.

Communications, Letters, etc., have been received from Messrs. Samuel, Liverseege, Shapley, Gandulph, T. C. H., C. J. B.

THE ESSENTIAL OILS OF BLUMEA LACERA, DC., AND SPHÆRANTHUS INDICUS, LINN.

BY W. DYMOCK.

These two plants attract attention in India during the cold weather by their abundance on waste ground and in fields after the harvesting of the rice crop. The *Blumea* has a powerful camphoraceous odour, and *Sphæranthus indicus* a rose-like perfume.

B. lacera is a perennial plant, with obovate, deeply serrated leaves and yellow groundsel-like flowers, the whole plant being thickly clothed with long silky hairs. The natives of the Concan, near Bombay, call it *Nimúrdi*, and make use of it to drive away fleas and other insects. One hundred and fifty lbs. of the fresh herb in flower was submitted to distillation in the usual manner with water, and yielded about 2 ounces of a light yellow essential oil, having a specific gravity of 0·9144 at 80° F., and an extraordinary rotating power, 100 mm. turning the ray 66° to the left. Mr. D. S. Kemp, who made the observation, checked it by examining a 10 per cent. solution in alcohol, which gave 6·6.

This *Blumea* is of interest as the possible source of an insect powder. I am forwarding a supply of the plant and a specimen of the oil to Mr. Holmes for experiment and also for identification, as the genus is a difficult one.

Sphæranthus indicus is an annual with sessile, decurrent, obovate, bristly serrate, downy, glutinous leaves, and globular heads of purple flowers. It is a well-known Indian medicine, under the names of *Múndi*, *Gorakhmúndi*, *Munditika*, *Murmuria* and *Kottak-karandai*, and is reputed to be a general tonic, deobstruent, alterative and aphrodisiac. The distilled water is recommended for use and also the root. One hundred and fifty lbs. of the fresh herb was distilled with water in the usual manner and yielded a very deep sherry coloured, viscid essential oil, very soluble in water, and clinging to the side of the vessel, so that only half an ounce could be collected. The oil does not appear to have any rotatory power, but it is difficult to examine on account of its opacity.*

Bombay, May, 1, 1884.

THE CHEMICAL PHARMACY OF THE NEW PHARMACOPÉE FRANÇAISE.

(*Continued from page* 919.)

Sulphur and the mode in which its preparations are described form a good illustration that the new Codex may lay claim to being more than an amended edition of a preceding work. It will be interesting to see the manner in which precipitated sulphur, (soufre précipité) is directed to be made.

Slaked lime has been rejected, and ordinary water (eau commune) gives place even here to aqua destillata. This absolute choice of eau distillée has raised the ire of French commentators.

Sulphur Præcipitatum. Magistère de Soufre.

Monosulphuret of sodium, in crystals	240
Sublimed sulphur	128
Distilled water	200
Hydrochloric acid, pure	230

* Specimens of the plant and oil are being forwarded for the Museum.

Put the sodium sulphide, sulphur and water, into a glass vessel of about the capacity of a litre, and raise nearly to ebullition over a sand-bath. As soon as the sulphur has quite dissolved, dilute with water and filter into a precipitating vessel of a capacity of from 5 to 6 litres. Bring up the volume to about 4 litres. Pour into this hydrochloric acid previously diluted with 4 parts of water. Pour the acid into the liquid, not the liquid into the acid. The mixture must be well agitated so that the acid should nowhere be in excess as regards the polysulphuret. Continue to add the acid, stirring always until a distinctly acid reaction is produced. Conduct the operation in the open air so as to avoid the fumes of sulphuretted hydrogen.

The whole of the sulphur is thus precipitated. Pour off the supernatant liquor; wash with boiling water until solution of silver nitrate gives no reaction. Dry and keep. Precipitated sulphur thus made is in a state of fine division, but not entirely free from the odour of sulphuretted hydrogen in spite of repeated washing.

Soufre Doré d'Antimoine (golden sulphuret of antimony) is retained, though described anew.

Kermès Minéral (oxysulfure d'antimoine hydraté) is not yet to pass away from continental pharmacy. It is prepared by precipitation, called Cluzel's method, the only one to be employed in medicine. Kermes made by fusing sulphuret of antimony, sulphur and potassium carbonate is reserved for veterinary practice.

Numerous sulphates and sulphurets are in the list, some which should be relegated to a manual of chemistry; in England we trust more to individual skill and less to official definition. Consequently many chemical substances have been omitted in this review; not because they are deemed unimportant, but, with our independent habits, their authorized formulæ are of minor interest.

The cinchona series has been the subject of a completely new investigation, and even when the old titles have been retained, the descriptive portion and methods of testing purity are of modern date.

This branch of pharmaceutical chemistry would be unfairly treated in brief abstract, and it must only be remarked that two novelties are, the sulfate de cinchonidine basique (needle-like crystals containing 6 equivalents of water) and sulfate de quinidine basique, not unlike in appearance the ordinary quiniæ sulphas.

Charbon animal purifié (carbo ossium acido depuratum), ordered in certain of the cinchona preparations, must invariably be used purified, owing to the calcium salts always found in the animal charcoal of commerce.

Charbon végétal (carbo ligni) is stated to have the greater absorbent power in proportion to the hardness of the wood from which it has been prepared.

Sulfovinate de Soude (ethyl sulphate of soda) has now a recognized position; the sulphovinates enjoyed a passing fashion in English prescribing.

The chlorhydrates will be noticed subsequently; the chlorures (chlorides) have been much extended.

Of these latter, the Chlorure Ferreux Cristallisé (ferrous chloride), not a very convenient preparation in itself, is a simple solution of iron filings, Tournure de fer, or Pointes de Paris, in hydrochloric acid, the iron being in excess. Filter, evaporate and crystallize. It is probably inserted for the preparation of the Chlorure Ferrique Dissous (liquor ferri perchloridi) made by dissolving the above crystals in water to a density of 1·10. Through the solution is passed a current of washed chlorine, till there is no blue precipitate by potassium ferricyanide. Concentrated solution of ferrous chloride is then added until no trace of chlorine is observed, care being taken not to add excess. The solution of ferric chloride is reduced to the density of 1·26 by addition of distilled water. Various lower strengths may be obtained on further dilution.

Fer Réduit (*Ferrum reductum*) has long been a favourite continental remedy. This is one of the few substances which remains described in almost the same words as in the Codex of 1866.

It is essential that the hydrogen employed should be absolutely free from sulphuric or sulphurous acids, else the contained sulphur, acting on the iron would give black sulphuret.

Moreover, the temperature must be nicely regulated. If reduction takes place below a dull red heat, the product is black and pyrophorous. If at a bright red heat, the iron particles cohere, and the requisite fineness is not obtained.

Ferrocyanhydrate de Quinine is a new introduction. The salt is described, but no process given.

Chlorure de Mercure (calomel) by volatilization; *Chlorure Mercureux Précipité* (white precipitate), and *Chlorure Mercurique* (corrosive sublimate) are all three supposed to be prepared by the pharmacien, full details of manufacturing process being given. A distinction in synonym used to be drawn between mercure doux (calomel obtained by sublimation); and calomel à la vapeur; both synonyms now apply to the one formula of the Codex.

Chloral Hydraté belongs to comparatively modern chemistry, and is now official. *Chloroform* is not a new introduction, but its mode of preparation and chemical characters have been written afresh, with indications of processes of purification to obtain it for anæsthetic purposes, and for medical use generally.

Acide Chrômique Cristallisé, replaces the old solution, and the Chrômate (bi) d'Ammoniaque has been added.

Citrate de Magnésie is what its name implies, and must not be confused with other preparations of a somewhat similar title belonging to galenical pharmacy.

Ethers are five in number:—Éther acétique, process and characters given. Éther amyl-nitreux (amyl-nitrite). Éther brômhydrique (ethylic bromide), process and characters given. Éther iodhydrique (ethylic iodide), process and characters, and éther officinal or pure, elaborate details of process and arrangement of apparatus being described.

Éther Rectifié du Commerce, commonly called sulphuric ether, is of two kinds, the first having a density of 0·724, and a second whose density is 0·735, but it is not sufficiently rectified, and contains water; about 8 per cent. of alcohol, and often other impurities. It should be reserved exclusively for veterinary use.

Glycerine has been removed from the list of materia medica, and placed in the chemical section; its applications belong to galenical preparations. When officinal or purified for medicinal use it should be free from colour and smell, with a sweet taste, and with no after bitterness. Density 1·242. On combustion it should leave no residue. Soluble in all proportions in water and alcohol, but insoluble in ether and chloroform. Its adulterations are, water in excess, dextrine, glucose, syrup and honey. In veterinary pharmacy there is an iodized glycerine (Glycérine Iodée, Trasbot.), made of equal parts of tincture of iodide and glycerine.

A new preparation is presented under the name of:—

Glycyrrhizine Ammoniacale.
Glyzine, Glyzina.

Rad. Glycyrrh. (Smyrn.)	200
Aq. destillat.	800
Acid. sulph. pur.	4
Liq. ammon. pur.	3

Bruise the liquorice root so as to reduce it to a sort of stringy tow, and macerate for four hours with twice its weight of cold distilled water. Press and strain and treat the residue in the same manner. Allow both macerations to deposit, decant, raise them to the boiling point, and filter them in order to separate the coagulated albumen. Unite the liquors, and when quite cold pour in by degrees sulphuric acid previously diluted with four times its weight of water till no further precipitate is produced.

This precipitate, at first gelatinous and flocculent, soon coheres strongly and forms a semi-soft mass at the bottom of the vessel. Pour off the supernatant liquor; wash repeatedly, and well knead the mass until completely free from acid.

Dissolve over the water-bath in the smallest possible quantity of liquor ammoniæ, diluted with an equal weight of water.

Thinly spread the solution on plates or glass, dry at 40° C. (104° F.) and scale. Colour, reddish brown, and translucent if the scales are not too thick.

Glyzine is completely soluble in distilled water, communicating to it an amber tint; sugary taste, much like that of rad. glycyrrhizæ, and it froths on agitation. It is insoluble in strong alcohol and in acid liquids.

Good Smyrna root should give from 6 to 7 per cent. of glyzine.

Iodhydrate d'Ammoniaque is our ammonium iodide, the remaining iodides being the mercurous, which is ordered to be prepared only in small quantity to avoid the danger of over-heating, and mercuric iodide, and the iodides of lead, potassium and sodium. Ferrous iodide now belongs to pharmacy proper, and iodide of sulphur has dropped out of existence.

Lactic acid is distinctly intended to be prepared at home, as not only a process is given for its manufacture, but the mode of its purification is indicated so that it should be in a fit condition to make the lactates which are specified further on. It must be confessed that in this respect we admire the French system of pharmacy, and believe that to a considerable extent the practice might be copied with advantage by ourselves.

The lactates are five in number: Lactate de chaux (lactate of lime) is purified for use. Lactate ferreux (lactate of iron) and lactate de zinc are the old preparations of 1866, but lactate of quinine is new. It is made by mixing powdered quinine hydrate in sufficient water; heating to the boiling point and adding enough lactic acid to dissolve the quinine, and to give a feebly acid reaction. Filter boiling and crystallize.

In appearance the salt much resembles the official sulphate. It is soluble in 3 parts of cold water, and in less than its own weight of boiling water. Very soluble in alcohol at 90°, and almost insoluble in ether.

Lactophosphate de Chaux en Solution (Liquor calcis lactophosphatis).

Phosphate of lime (neutral) . . .	17 grams.
Lactic acid, pur.	about 19 grams.
Aq. destillat.	964 grams.

Carefully suspend the phosphate in the water; add the lactic acid and allow a few minutes for solution to take place. Filter. Twenty-five centigrams of neutral phosphate of lime are contained in 15 grams of the solution.

Mercury, as obtained in commerce, should be reserved exclusively for mercurial preparations intended for external use. For other purposes it must be purified by nitric acid, diluted with twice its volume of water. Keep it in contact for four and twenty hours with frequent shaking. Decant the supernatant liquor; wash and dry.

Oxygen gas comes once more into the domain of pharmacy, and is ordered to be prepared from potassium chlorate and manganese dioxide.

The oxides, which we generally term such, are about ten in number, and are familiar to English pharmacy.

Oxyde (Sesqui) de Fer Bi-Hydraté, or ferric hyhydrate, is to be prepared by the addition of liquor ammoniæ to solution of perchloride of iron, both previously diluted. A reddish-brown precipitate is formed with alkaline reaction. Collect and wash till the water used, acidulated by nitric acid, has no effect on silver nitrate. Hydrated peroxide of iron is to be kept as an antidote to arsenious acid; and the more freshly prepared the better. Experience would suggest the advisableness of extemporaneous manufacture: its keeping properties are small.

With regard to Oxyde Mercurique Rouge, or red precipitate, when heat is too long employed the oxide is decomposed into oxygen and mercury. On the other hand when not heated sufficiently to decompose all the nitric acid used, an oxide is obtained mixed with subnitrate of mercury. This second inconvenience is to be more carefully avoided than the first. Oxyde de Zinc is prepared both by calcining hydrocarbonate of zinc obtained by precipitation; and by the direct calcination of metallic zinc. The first process is called par voie humide; and the second, par voie sèche, the result being Fleurs de Zinc.

Acting probably on the theory that pepsine is now well known and that the literature of the subject is abundant, the short essay contained in the former Codex has been abandoned; no process for its extraction is supplied, and only a test of purity is appended.

Pepsine médicinale is described as a greyish-white powder which is a mixture of extractive pepsine and starch.

Extractive pepsine is made from the stomachs of pigs, or from the rennets of sheep or calves. It should dissolve in water without sensible residue.

A variation of the old test is given in which hydrochloric acid replaces lactic acid; and 50 centigrammes, instead of 25 centigrammes, of pepsine should dissolve 10 grams of fibrine.

Test for Medicinal Preparation.

Put into a small wide-mouthed bottle—

Medicinal pepsine	50 centigrammes.
Aq. destillat.	60 grams.
Acid. hydrochloric. pur. . .	60 centigrammes.
Fibrine (pig) washed and freshly dried	10 grams.

Place the bottle in a hot water drying closet, temperature up to 50° (122° F.) and digest for six hours with frequent agitation till the fibrine is quite dissolved. Ten c.c. of the cold filtered solution should not be affected by the addition of from 20 to 30 drops of nitric acid.

Extractive pepsine (that is the unmixed article) should require only 20 centigrammes to produce the same result.

(*To be continued.*)

QUINOVIN AND QUINOVIC ACID.*

BY C. LIEBERMANN AND F. GIESEL.

Notwithstanding the occurrence of quinovin and quinovic acid in most if not all species of china and cinchona barks and their varieties in considerable quantities (up to 1·6 per cent.), both compounds have only been imperfectly investigated. The older work of Pelletier and Caventou, Winckler, Petersen and Schnedermann, did not go much beyond the preparation and analysis of quinovin, and it is to the investigation of Hlasiwetz that some further conclusions as to the glucosidal nature of quinovin and respecting its decomposition product, quinovic acid, are due. The object which the authors sought to attain was to throw some light upon the chemical nature and formulæ of these compounds, and the present paper contains a preliminary statement as to the results.

The quinovin used in the experiment was a waste byeproduct in the manufacture of quinine, obtained when the cinchona alkaloids are extracted with alcohol. The bases and their salts, together with quinovin and numerous other compounds, pass into alcoholic solution. Upon distilling off the alcohol from the filtrate, and treating with a dilute mineral acid, only the bases in the state of salts are dissolved from the residue by water, leaving a brown resinous mass, insoluble in water, which was the raw material used.

This insoluble substance was digested with milk of lime at a moderate temperature and the filtrate precipitated with hydrochloric acid. The pale yellow precipitate was dried and digested with alcohol, when a small quantity of quinovic acid remained undissolved as a white powder whilst the greater part of the mixture went into solution with a brown colour. Upon diluting this solution with water until a precipitate commenced to form and allowing it to stand for some time a separation took place of small, slightly coloured crystals of quinovin. A single recrystallization from dilute alcohol was usually sufficient to obtain it free from quinovic acid, in the form of small glittering white scales. The yield of the pure product is not very favourable (about 26 per cent. of the crude material), as a considerable proportion of the crystallizable quinovin is kept in solution by the amorphous products. This can be proved by the fact that boiling hydrochloric acid will still split off from it a considerable quantity of quinovic acid, for which the mother-liquor may, therefore, be worked.

A resinous raw material obtained from other barks in a precisely similar manner yielded, however, no quinovin. This was the case when cuprea bark, derived from the nearly allied species *Remijia*, was used. The alcoholic solution of the resin, diluted with water, could not be

* Abstract of a paper read before the German Chemical Society (*Berichte*, xvi., 926).

brought to yield crystals, notwithstanding that the formation of a considerable quantity of quinovic acid upon heating it with hydrochloric acid implied the presence of a large quantity of quinovin. Eventually the separation of the body yielding the acid was effected by converting it into an ammonia compound. The alcoholic solution was treated with the requisite quantity of strong ammonia and heated, when after a short time the whole mass formed a crystalline paste of the ammonia compound in fine needles. This was freed from mother-liquor by pressure, decomposed with acetic acid to take up the ammonia, dissolved in alcohol and the ammonia compound again formed and decomposed. Upon then diluting the alcoholic solution with water to the point of turbidity, a crystallization of fine white needles resulted. A further investigation showed that this substance obtained from cuprea bark agreed with the quinovin previously studied in composition and in splitting off quinovic acid, but that it was not identical with it, though probably an isomer. It was therefore named β-quinovin

The authors, having been able to prepare a considerable quantity of these two compounds in a crystalline condition (quinovin having been represented by most previous writers as an amorphous substance), were able to study them and their derivatives advantageously.

a-Quinovin is described as a white, very light crystalline powder, readily reduced to a dust. It is quite insoluble in cold water and almost insoluble in hot, but is soluble in cold aqueous solutions of the alkalies and ammonia, in milk of lime and baryta water. In benzol, chloroform and absolute ether it is very difficultly soluble; but it dissolves more readily in dilute alcohol, and is separated from it, upon a suitable addition of water, in glittering white scales. From stronger alcohol it separates in rosettes of clear very small needles. It is very freely soluble in 98 per cent. alcohol, especially when warmed gently, 100 parts of alcohol dissolving at 15° C. more than 43 parts of α-chinovin, without any separation taking place upon standing. Upon evaporation of the alcohol over sulphuric acid the whole dries finally to a gummy mass, without any separation of crystals. α-Quinovin in solution has a dextro-rotatory action: $\alpha = +56{\cdot}6$. It does not reduce Fehling's solution, and does not undergo fermentation with yeast. It is a very stable compound, some raw material having been found unaltered, after having been kept six years. Powdered quinovin has a very bitter taste. In concentrated sulphuric acid it dissolves, under evolution of carbonic oxide, with an orange-yellow colour. In fuming nitric acid it dissolves without any specially energetic reaction; but with glacial acetic acid the solution is faintly blue, which colour is also shown by the precipitate thrown down by water. Analyses of five samples purified in different ways and dried at 120° C. gave—

	I.	II.	III.	IV.	V.
C. . . .	65·15	65·26	65·29	65·75	65·92
H . . .	8·75	8·97	8·85	8·88	8·98

Samples IV. and V. were the most carefully prepared. The figures for carbon are about 1 per cent. lower than those found by Schnedermann.* Drying at 160° to 190° C., as recommended by Hlasiwetz,† is thought by the authors not to be advisable, as some of the water removed from a glucoside at this temperature would possibly be water of constitution.

β-Quinovin is in most respects very similar to α-quinovin, so that the characters already referred to the latter also apply to β-quinovin. Nevertheless, sharp distinctions between the two compounds are not wanting. The β-compound, unlike the other, is not soluble in absolute ether or acetic ether. From dilute alcohol it crystallizes readily in handsome scales. But its most characteristic difference from the α-compound is its behaviour towards absolute (98 per cent.) alcohol, in which β-quinovin is also freely soluble, with the liberation of heat, generally small in quantity, but easily recognizable with a thermometer. After some time, even if evaporation of the alcohol be prevented, a separation of crystals commences spontaneously. This phenomenon was most remarkable in a case where 100 grams of quinovin were dissolved in 420 grams of absolute alcohol. By the following day 118 grams of glassy crystals had separated, which exposed to air effloresced and lost weight until it reached 93 grams. In the 400 grams of alcoholic mother-liquor only 7 grams of quinovin remained dissolved. It appears therefore that the β-quinovin is reprecipitated from absolute alcohol, in which it is so soluble, almost completely in the form of an alcohol compound. The finest crystals are obtained when a solution of β-quinovin in twenty-five times its weight of absolute alcohol is allowed to evaporate slowly from a deep glass over sulphuric acid; but when removed from the liquid the crystals effloresce and become opaque with extraordinary rapidity. When heated in a melting-point tube these crystals melt in their crystallization alcohol between 70° and 80° C.; at 120 C., when the alcohol is all driven off, the substance again becomes solid, and it fuses like quinovin, under decomposition, at 250° C. Triturated with concentrated sulphuric acid on a watch glass β-quinovin forms a yellow solution, which exposed to air becomes a beautiful cherry-red; α-quinovin shows this reaction, but far more faintly. In rotatory power β-quinovin is the least active by one-half: $\alpha = +27{\cdot}9$.

Decomposition of the Quinovins.—The decomposition into quinovic acid and sugar, first observed by Hlasiwetz, is shown by both α- and β-quinovin. It is effected by sulphuric acid as well as hydrochloric acid in alcoholic solution; but a solution containing 5 per cent. of sulphuric acid is not completely decomposed even after several hours' heating at 100° C. In the splitting up of small quantities (10 to 50 grams) for determining the yield of quinovic acid, it was found most advantageous to dissolve the quinovin in the smallest possible quantity of alcohol and allow the solution saturated with gas to stand in a closed vessel thirty hours. The decomposition was complete; all the quinovic acid had so completely separated as a heavy white crystalline powder that the small quantity of coloured supernatant liquid gave no precipitate with water. Quinovic acid may, however, be prepared direct from the brown resinous raw material, by dissolving it in alcohol and then heating it several hours upon a water-bath with much concentrated hydrochloric acid. The gelatinous quinovic acid which separates is white, notwithstanding the strongly coloured mother-liquor. It is washed with alcohol, in which it is insoluble, and then dissolved in it by the aid of ammonia. If the ammonia be boiled off, or hydrochloric acid be added with heat, the quinovic acid falls as a pure white sandy powder that can be easily filtered. The yield by this treatment equals about 60 per cent. of the raw material.

It was ascertained that both the quinovins yielded identical decomposition products and in almost the same proportions, the average yield of quinovic acid obtained from α-quinovin being 74·8 per cent., and from β-quinovin 77·2 per cent. The identity of the quinovic acid from the two compounds was determined not only by their general properties, but by the behaviour of their derivatives.

Quinovic Acid has been already pretty thoroughly described by Hlasiwetz. It forms a snow-white powder consisting of small needles, quite insoluble in water and soluble with great difficulty even in boiling alcohol or glacial acetic acid. It is best brought into solution by adding ammonia to the alcohol; after filtration it may be set free again by the addition of acetic acid.

Quinovic acid is soluble in ammonia, the alkalies and alkaline earths, though far less acid dissolves than would suffice for their saturation. The ammonia and lime salts

* *Annalen*, xlv., 277.
† *Annalen*, lxxix., 148.

crystallize from alcohol in needles, the former losing its ammonia in the air or by boiling its alcoholic solution. The alkaline carbonates are decomposed by quinovic acid. The alkaline solutions froth like a solution of soap.

If an alkaline solution of quinovic acid be precipitated by acids it separates in a gelatinous form, the entire contents of the vessel solidifying. In this condition, which probably represents a special hydrate of quinovic acid, the acid is remarkably soluble in ether and even in alcohol. The reaction can, therefore, be utilized in the recrystallization of the acid, which separates from ether in needles. Upon boiling or allowing the liquid to stand for some time, the acid passes from the soluble modification into the insoluble form. The authors did not find that quinovic acid possessed a regular melting point; it softens at 295° C., giving off at the same time carbonic acid. Analyses of the substance dried at 120° C. gave the following results, I., II. and III. representing quinovic acid from α-quinovin and IV. and V. from β-quinovin:—

	I.	II.	III.	IV.	V.
C . . .	72·55	72·32	72·47	72·37	72·29
H . . .	9·26	9·24	9·47	9·86	9·34

These results vary slightly but constantly from those obtained by Hlasiwetz, who with a substance dried at 160° C. obtained in seven analyses an average of 73·60 per cent. of carbon and 9·85 per cent. of hydrogen, from which he calculated the formula $C_{24}H_{38}O_4$.

The authors failed to obtain salts of quinovic acid of sufficient purity to allow of their being used in estimating the equivalent of acid.

Quinovin Sugar.—In preparing the other decomposition product of quinovin, the quinovin sugar of Hlasiwetz, the alcoholic hydrochloric acid solution of quinovin is kept sheltered from air and light until nearly all the quinovic acid has separated (about twenty-four hours), then filtered, and the filtrate exactly neutralized with strong soda solution, and evaporated rapidly to dryness. The saline mass is boiled with absolute alcohol, the solution evaporated to dryness and the residue again taken up with a little absolute alcohol. The sugar is present then in the alcohol free from ash, but contaminated with a little quinovic acid, which may be precipitated from the concentrated alcoholic solution in flocks by boiling it with some water. The quinovin sugar is then filtered out and taken up once in absolute ether, in which it is remarkably soluble, and in this way it may be obtained containing only a little colour, which can be removed by animal charcoal. Quinovin sugar has a sweet taste with a bitter after-taste. Dried in a vacuum it resembles a colourless glass; it is highly hygroscopic, and could not be obtained in a crystalline form. At 105° C. it liquefied and gave off an odour of caramel. The following results were obtained upon analysis:—

	Found		Calculated for $C_6H_{12}O_4$	Calculated for $C_{12}H_{22}O_8$
C . .	48·98	48·90	48·65	48·98
H . .	8·12	8·18	8·10	7·49

The sugar from α- and β- quinovin was identical. It reduced Fehling's solution; but did not ferment with yeast, even after boiling with acid. It is dextro-rotatory; the β- sugar giving $\alpha = 78·1$

Decomposition Products of Quinovic Acid.—The authors report that they have succeeded in splitting up quinovic acid in two directions. When heated to about 300° C. under ordinary atmospheric pressure, or preferably to a lower temperature in a partial vacuum, carbonic acid is evolved leaving about 80 per cent. of a new acid (*pyroquinovic acid*), mixed with some resin, from which it can be freed by dissolving it in ether and shaking the ethereal solution with strong solution of potash, when the potash salt separates at once in white flocks of crystalline needles. Pyroquinovic acid melts, with previous softening at about 216° C., and distils unaltered at a temperature above 360° C. It is insoluble in acids, very difficultly soluble in petroleum spirit, but readily soluble in cold alcohol, ether, benzol, and glacial acetic acid, though an acetic compound separates, after a time from the last mentioned solution in clear crystalline plates. The alkaline solutions froth. *Novic acid*, the other decomposition product, is obtained when finely divided quinovic acid is dissolved in concentrated sulphuric acid. An active evolution of carbonic oxide takes place and when the reaction has ended the mass is thrown into water, the precipitate dried on porcelain and then dissolved in ether and the solution shaken with strong alkali solution. On standing the liquor separates into three layers, the middle one containing the potash salt of the new acid. The free acid crystallizes from benzol in colourless transparent needles, melting at 257° C. The top ethereal layer yields upon evaporation a yellow resinous mass, which can be crystallized from boiling alcohol in beautiful yellow needles. This substance, which gives several interesting colour reactions, has been named "chinochromin."

From the general results of the analyses the authors are inclined to represent these compounds by the following formulæ:—

Quinovin	$C_{38}H_{62}O_{11}$
Quinovin Alcohol Compound . .	$C_{38}H_{62}O_{11} + 5C_2H_6O$
Quinovic Acid	$C_{32}H_{48}O_6$
Pyroquinovic Acid	$C_{32}H_{48}O_4$

But some of the analytical results agree nearly as well with formulæ containing another atom of carbon, and at present the authors prefer to leave the question open.

THE SEPARATION OF MERCURIC FROM MERCUROUS IODIDE.*

BY H. MACLAGAN.

According to most authorities, the separation of these two salts is a very easy and simple matter, the process being to treat the powder with certain solvents, such as alcohol, ether, etc., which are supposed to dissolve out the red without action on the other.

I have lately had to perform some analytical work in this line, and was at first considerably puzzled at the singular results obtained. A sample of mercurous iodide, which was believed to be pure or nearly so, was washed with ether, sp. gr. 0·725, and the liquid, on evaporation, left a yellowish residue, which became red when rubbed. After several washings, the result was weighed, and amounted to about 1 per cent. The washings were then continued, using the same quantity of ether for each, and weighing after each evaporation, with the result of a *steady* and *uniform* increase until 6 per cent. was reached, when the washings were discontinued. The salt had become quite dark coloured, and metallic mercury was easily seen with the microscope. A quantitative analysis had shown that, making the usual allowance for loss, the iodide was pure, and this, added to the fact of the singular uniformity in the ratio of increase in weight of the deposit, and the fact that the total amount of red iodide obtained should have been soluble in one-tenth of the solvent used, pointed out clearly that it was being derived from the yellow iodide through some action of the ether. I have made a series of experiments to prove this, using different solvents of red iodide, and, as far as I have been able to ascertain, there is not a single one which does not more or less decompose mercurous iodide. Those experimented with were ether, sp. gr. 0·718; ether, sp. gr. 0·725 (Squibb's); ether, 0·725, and alcohol, 0·820, equal parts; alcohol, 0·820, and chloroform. In each case 1 gram of iodide was treated with six successive washings of 25 c.c. each of liquid, shaken occasionally at intervals of half an hour, and as much as could be poured off, filtered into a watch-glass and evaporated on the top of a drying oven, where the tem-

* From the *American Druggist*, May, 1884.

perature was about 120° F., the weight being noted after each evaporation. The results were as follows, the figures representing the weight in grams of the dry residue after evaporation of the solvent: —

	No. 1. Ether, 0·718.	No. 2. Ether, 0·725.	No. 3. Ether and alcohol.	No. 4. Alcohol, 0·820.	No. 5. Chloroform.
1st.	0·0029	0·0044	0·014	0·0046	0·0007
2nd	0·0029	0·0044	0·0118	0·0045	0·0007
3rd	0·0026	0·0043	0 011	0·0044	0·0007
4th	0·0034	0·005	0·0129	0·0031	0·0009
5th	0·0028	0·0046	0·0105	0·0934	0·0009
6th	0·0029	0·0049	0·0135	0·0042	0·0007
Total	0·0175	0·0276	0·0737	0·0242	0·0046

The residues from Nos. 1, 2, and 5 were yellowish, but became red when rubbed, those from the rest were red. The iodide in Nos. 2 and 3 perceptibly darkened on the addition of the first 25 c.c., and at the end they were of a dirty greenish colour; the other three were only slightly discoloured. The residues on the glasses were then treated each with its original solvent to ascertain about the quantity necessary for solution.

No. 1 dissolved in 13 c.c., No. 2 in 10 c.c., No. 3 in 10 c.c., No. 4 in 6 c.c., No. 5 in 10 c.c. Thus showing that had the red existed primarily in the salt it should almost all have been obtained in the first washing. For additional proof of this 2 per cent. of red iodide was added to the same salt previously used, and one gram of the mixture treated with 25 c.c. of chloroform; the result was 0·0185, and a second 25 c.c. yielded 0·003. Next, 1 gram of iodide was shaken as before with 30 c.c. of ether, sp. gr. 0·725, the ether filtered into a second bottle containing 1 gram of iodide, and shaken from this into a third, then into a fourth, and, finally, into a watch-glass and evaporated (30 c.c. was used here, so as to have about 25 c.c. for the last gram). The deposit weighed 0·0049, the same as obtained previously from only 1 gram, and the salt in the first bottle darkened, while the other three were unchanged. One *decigram only* of iodide yielded by treatment with the same ether 0·0047, and the residual salt in the bottle was treated with a large quantity of ether, the dark coloured sediment collected on a filter and dried, a globule of mercury resulting.

The iodide used in these experiments was made by double decomposition of mercurous nitrate and potassium iodide, and fulfilled all the requirements of the U.S.P. An analysis of it showed

$$\left\{\begin{array}{ll} Hg & 607 \\ I & 386 \end{array}\right\} \text{ theory requiring } \left\{\begin{array}{ll} Hg & 611 \\ I & 389 \end{array}\right\}$$

Iodide made in the officinal way gave precisely similar results.

It seems clear from these facts that there is some principle in these solvents (probably the same in all, as they are closely related) which decomposes mercurous iodide, and, therefore, while sufficient for ordinary purposes in separating the two iodides, they cannot be used for analytical work without making proper allowance, and this allowance must probably be determined in each case. As indicated, chloroform is to be preferred, and of that, 25 c.c. will dissolve about 20 milligrams of mercuric iodide.

GINSENG CULTIVATION IN JAPAN.

The following particulars are taken from a United States official report on the method of cultivating ginseng, written by Yamaguchi Sheiguro, and forwarded by Minister Bingham, and translated by Mr. Whitney, interpreter, U. S. Legation:—

The seed of ginseng may be sown twice a year, namely, during the vernal and autumnal equinoxes; but in this district (village of Meiyama, county of Aidzu, province of Iwashiro, about 37° N. latitude, 140° E. longitude from Greenwich) the seed is usually sown during the autumnal equinox. The land on which the seed is to be sown is permitted to lie fallow for one year, and during the year following the grass is cut and buried in the soil for the purpose of fertilizing it.

In April of the same year the land is ploughed. Before the period called Taisho (commencing about the 22nd day of July) begins, horse manure and straw used in the stables are spread over the surface and the clods of earth are broken up, and the land is divided into mounds each about 3 feet broad for sowing purposes. By means of the *meita*—a board about 2 feet in length, 11-3 feet in breadth, in which is inserted a stick about ½ foot long, sharpened at one end—the surface of the mounds is smoothed and the seed is sown in drills made with the *meita*. After sowing the surface of the mounds is lightly swept with a broom, and, in order to protect the surface from the sun, straw about 1 foot thick is spread over it. Before the period called Ko Kun (commencing about the 20th day of April of the ensuing year) begins the straw is removed, and on both sides of the mounds sticks about .5 feet long are erected about 6 feet apart, on which cross-bars are placed, over which straw mats are laid to protect the surface of the mounds from the sun, the sticks on the north side of the mounds being higher than those on the south. Until the period of Taisho (about the 22nd day of July) returns, the ground must be kept carefully weeded, and, during the first two years, the soil between the shoots of the ginseng must be hoed about seven or eight times, after which no weeding is required on account of the shoots being considerably grown.

When the period called So Ko (commencing about the 23rd day of October) begins the colour of the leaves becomes yellow, and the straw mats should then be removed. Twenty days after the period called Doyo, which begins about the 18th day of January and continues seventeen or eighteen days, the field should be manured. The quantity of manure for every tan (about ¼ acre) should be one *kan* and two hundred *me* (=7½ catties=10 pounds) of oil cake, 6 sho (1 sho=109·752 cubic inches, 'Hepburn's Dictionary') of rice bran, and a quantity of night soil diluted with water. The quantity of manure for every *tan* must be doubled in the second year and trebled in the third year. In July of the fourth year the roots are dug up and dried. Ginseng is, during its growth, attacked by the mole, the rat, and a worm about 2 inches long, called *hari-gane-mushi* (wire-worm), from its resemblance to a piece of wire. Of these the mole burrows in the field and overturns the roots of the ginseng, so that the plants finally die; the rat follows the holes made by the mole and eats the roots, consequently the latter is more injurious than the former. The following means are used to protect the plants against these pests:—

In order to prevent the mole from burrowing, boards about 1 foot square are inserted in the ground on all sides of the mounds so as to stop up the holes, or jars are buried here and there between the mounds, or pit-falls are made in the holes. In order to keep off the rat a bamboo tube filled with gunpowder is placed in the mole hole and the powder ignited, and the smoke remaining in the hole prevents the rat from approaching. In order to protect the roots from injury by the *hari-gane-mushi* (wire-worm), onions, leeks, or dai kon (a kind of large radish) are planted between the mounds about 1 foot from one another; and when the worms attack these vegetables, the vegetables are pulled up and the worms killed. These vegetables are planted for the purpose of attracting the worms.

The roots of ginseng having been dug up a portion of the stem about 3 inches long is cut off and the roots are washed in water with a brush.

Then the fibrous portion of the root about 1 inch long is removed—these fibres, called *moniku* (literally hair flesh), are used as a medicine, and the remaining parts are scraped with a bamboo knife for the purpose of removing the particles of soil.

After these steps have been taken all the roots are classified into five species or grades, according to their qualities. Those roots which are large but injured are called Omare (literally large and rare), and those which are small and injured Sho mare (literally small and rare). The *moniku* or fibres are sometimes classified as the sixth and seventh species. All the roots are then put upside down into baskets made of bamboo, each containing about one *kammi* (8·33 pounds) in weight of the roots. The baskets are then placed for five minutes in a liquid specially prepared, and which is boiling.

In preparing the liquid the following steps are prescribed: 5 *momme* (=1-24 pound=2-3 ounce) of ginseng, manufactured in the preceding year. 25 *momme* of liquorice root, and 25 *momme* (3 1-3 ounces) of *shai-shin* (a drug) are thrown into (2) *to* and 5 sho, or 25 sho (about 10 gallons) of water, and when the colour of the water becomes brownish the residue of these substances is removed and 7 1-5 *go* (1 *go*=53·475 cubic inches) of alcohol is added to the liquid. The roots of the lowest quality of ginseng are first boiled in the mixture and then all the other species are successively boiled therein, from the lower to the higher qualities.

They are immediately dipped into cold water, and when entirely cooled they are dried.

After ten baskets of ginseng have been boiled the liquid should be changed. A place open to the sunlight is to be selected for drying the ginseng.

The process consists in setting up a shelf with a shade made of split bamboos. On the shelf the roots are dried. During the daytime the roots must be turned over six or seven times; at night they are kiln-dried.

After about three days the skin becomes tolerably dry, and the roots become pliable. The stems and fibres are then entirely removed and the crooked roots are straightened.

After this they are again dried for four or five days; if the weather be rainy they are kiln-dried. The whole process of preparation now being completed it remains only to put them in cases, first wrapping them in thick paper.

There are two or three other methods of cultivation, but they are mainly the same as the method described in this paper.

The quantity of seed required for planting one acre is about half a bushel.

THE USE OF NAPHTHALINE AS AN INSECTICIDE.*

Naphthaline, in one form or another, has for some time been used by entomologists as a means of preventing injury to their collections from acari, psoci, dermestes, anthreni, and other museum pests. My own experience is that it destroys the acari and psoci, but not the other pests, though it tends to repel them. Recent investigations would seem to indicate that it may be used to advantage in the field as an underground insecticide. It appears that as early as 1842 a French physician, Rossignon, pointed out the possible use of naphthaline not only as a remedial agency in medical practice, but also as a substitute for camphor for the destruction of museum pests. But up to the appearance of the grape phylloxera in France no serious experiments were made with it in the field. Among the substances tried against this pest naphthaline played its part. The efficient ingredient in the "poudre insectivore" of Peyrat, was, according to Maurice Girard, naphthaline; but the experiments with it did not yield encouraging results.

Baudet recommended it to the French Academy in 1872, while in 1874 E. Fallieres proposed gypsum saturated with naphthaline, the mixture to be distributed over the soil. It was also among the numerous substances experimented with by Messrs. Maxime Cornu and P. Mouillefert, the results of which were published in the well-known memoir presented by these gentlemen to the French Academy in 1877. Naphthaline, up to this time, proved to be of little value in killing the insect, and of no value as a repellant. Nevertheless, Dr. Ernst Fischer, of the Strassburg University, encouraged and induced by the most favourable results obtained with naphthaline as an antiseptic and as a destroyer of micro-organisms (moulds, schizomycetes, bacteria, etc.), has, since 1881, again experimented with it as a direct remedy for the phylloxera; and he has given us the results of his experience in an interesting *brochure* lately received. The first part of Dr. Fischer's work treats of, and strongly recommends, the use of naphthaline for surgical purposes as an antiseptic superior, in most respects, to all other antiseptics now in use. His conclusions are based on extensive experiments showing the effect of the material on the lower organisms, and prove that, properly used, it not only arrests the growth of these micro-organisms but eventually destroys them. This part of the work will be of especial interest to those who are experimenting with a view of destroying disease-germs. It is to the second part that I would here call attention. Preliminary to a statement of the results of this part of Dr. Fischer's work, a few facts in regard to the nature of the substance may not be out of place.

Naphthaline, a carbohydrate of the formula $C_{10}H_8$, was first made in 1820, by Garden, from coal tar. It is volatile at any temperature, melts at 79·2° C., boils at about 214° C., and has a specific gravity of about 1·1. Essentially insoluble in water, alkalies and diluted acids, it is easily soluble in ether, hot alcohol, hot concentrated sulphuric acid and in many volatile and rich oils. It is readily carried off with aqueous vapours, so that in order to quickly disinfect a room, it is only necessary to heat a vessel with water in which naphthaline has been put. The naphthaline gas mixes very readily with atmospheric air, and is also readily taken up by water. It is not poisonous to man or to the higher animals, and for surgical purposes should be used chemically pure. The crude material is by far cheaper, and upon inquiry Dr. Fischer found that in London it can be obtained, without barrels, at 25 marks (6 dollars) per 1000 kilograms (about 2200 pounds), in Paris at 100 francs, and] in Cologne at about 45 marks (barrels included). The crude naphthaline contains more or less phenol and creasote, and is a stronger insecticide than the purified article, but also more injurious to plants. Dr. Fischer used the purified naphthaline in his experiments on phylloxera, but thinks that with some precaution the crude material might safely be used, especially if it is not brought in direct contact with the plant, or if used in the dormant season.

The experiments with phylloxerized grape vines were carried on under direction of Dr. Fischer at La Grave d'Ambares, near Bordeaux. Fifteen badly infested stocks,* partly growing on light, partly on heavy soil, were treated in April, 1883.

It was placed in a hole dug in the ground near the main root, and subsequently covered up; and the quantity used was on some plants one, and on others one-half kilogram. On September 18, the plants were examined with the following result:—All plants experimented with, but especially those treated with the largest quantity of naphthaline, showed a new and healthy growth of numerous long, fine rootlets, which were perfectly free from phylloxera; in fact, the phylloxera had entirely disappeared from the roots of all plants experimented with, whereas several plants not treated with naphtha-

* 'Das Naphtalin in der Heilkunde und in der Landwirthschaft.' Von Dr. Med. Ernst Fischer. Strassburg: Trubner, 1883. Reprinted from the *Oil, Paint, and Drug Reporter*, May 14, 1884.

* It is not stated whether the roots of these stocks were examined at the time, to ascertain whether or not the phylloxera was still at work.

line showed no young growth of rootlets, and an abundance of phylloxera. The growth above ground of the plants treated showed no difference as compared with plants not treated—a fact explained by insufficient time for the treated plants to recuperate. Some of the most vigorous new rootlets were found to have penetrated the layer of naphthaline, thus showing that the latter has no injurious influence upon them. A considerable quantity of the naphthaline was found unchanged at the date of examination, which shows that the evaporation is very slow, and that its effects will be correspondingly lasting.

The results are certified to by official affidavits, and were more marked on plants growing in heavier and moister ground than on those in light and gravelly soil.

As the most convenient mode of application, Dr. Fischer recommends that about 1 kilogram of the naphthaline be put in a trench dug around the plant a few inches from the stock; the trench to be not less than from 15 to 20 centimetres deep, and to be at once filled up again. He attributes the failure of former experiments: 1. To the small quantity of the material employed. 2. To its being employed too near the surface of ground, so as to permit evaporation in the air. He also thinks that results were expected after too short a lapse of time.

OLEUM GAULTHERIÆ.*

BY ISAAC EDWARD LEONARD, PH.G.

Oil of wintergreen was first made in Luzerne county, Pa., in 1863, from which time it has been distilled in great quantities, with the exception of last year, when the yield was not so plentiful, owing to the destruction of the shrubberies by the fire which passed over our mountains.

In distilling, the entire overground portion of the plant is employed, which has its greatest yield during the months of July and August.

The still is generally a wooden box, about eight feet long, four feet wide, four feet high, with a copper bottom and staid with bolts. The head of the still is copper, and connecting with this is a square or circular worm of the same material or of tin, placed in a barrel. The still being filled with wintergreen to within about twelve inches of the top, a sufficient quantity of water is added, and this is allowed to macerate from ten to twelve hours. The fire being started, the distillation commences and continues for about eight hours; but during the first two or three hours, 90 per cent. of the oil has passed over. For collecting the distillate, most of the distillers use a wide mouth bottle or fruit jar, fitted with a large cork having two holes. A small tin or glass funnel is put into one of the holes, so that the beak of the funnel is below the shoulder of the receiving vessel, and connected with the other hole is a suitable pipe forming an egress. The distillate passes into the receiving vessel through the funnel. It is here that the oil and the water separate, the oil going to the bottom, and the water being lighter and in excess passes through the egress pipe into a larger receptacle, where it is reserved for a subsequent operation (cohobation).

Occasionally the oil is very highly coloured. I have found several samples to contain traces of iron, which is due to the oxidation of the tin worm or can with which the oil comes in contact. Tin worms are used on account of their cheapness, but will only last about two weeks, before they undergo oxidation.

The wholesale dealers that handle the oil in large quantities have three ways of "cleaning" it, re-distillation, filtration and decolorization. The first two processes are easily understood, while the decolorization seems a difficult one, but is much easier than either of the others. The oil to be decolorized is put into a bottle and crystals of citric acid are added, the whole allowed to stand, agitating occasionally, until the oil is colourless, or nearly so.

On experimenting with nine quarts of wintergreen fruit, I found it contained one and a half drachms of oil. The chief uses of the oil are for flavouring and in printing fine calicoes.

In experimental distillation, I found that the lower specific gravity is due to the separating of the oil from the water too quickly, and that the higher specific gravity is obtained by letting the distillate stand from twenty-four to forty-eight hours before separating the oil from the water.

A case of poisoning occurred in 1883, at one of the grocery stores in White Haven, Pa. A man mistaking the oil for the milky water, drank about two ounces; he was taken to his home in Easton, Pa., and died in about five hours.

Parties have tried to export the oil, but did not succeed.

WEST INDIAN EPIPHYTES.

A. F. W. Schimper describes, in great detail, in the *Botanisches Centralblatt*, the various epiphytes natives of the West Indies. They belong to a great variety of families. Of species the largest number belong to the Orchideæ, but in the mass of individuals, to the Bromeliacæ and Aroideæ; next follow the Filices, Rubiaceæ, Gesneraceæ, Ericaceæ, Cactaceæ, Myrsineæ, Melastomaceæ, Bignoniaceæ, Clusiaceæ, Piperaceæ, Urticaceæ, and Cyclantheæ. They are usually herbaceous, but very often of considerable dimensions, less often woody.

The subject is treated under three heads, viz.:—(1.) General remarks on the epiphytic flora of the West Indies. (2.) The structure of the different species. (3.) The influence of their mode of life on their geographical distribution.

As far as regards their mode of life, they may be classified into four groups, viz.:—(1.) Those in which the adaptations are very simple; deriving their nourishment entirely from the *detritus* of the bark to which they are fixed. (2.) Those that derive their nourishment through aerial roots which reach the ground. (3.) Those in which the roots form a conspicuous spongy mass, in which great quantities of moisture and humus are collected; and (4.) Those in which the leaves perform the ordinary functions of roots in absorbing water and nutrient salts.

The special contrivances in particular cases are described in detail.

KOUSSINATE OF SODA.*

One of the most efficient combinations of koussin is that with soda, which is effected as follows:—Any desirable quantity of koussin is dissolved in hot water, to which enough bicarbonate of soda is added to dissolve the koussin entirely; boil this solution with a little animal charcoal for a few seconds and then filter. The solution thus obtained, and which though slightly coloured is clear, is now slowly evaporated in a porcelain dish until dry. The koussinate of soda is an amorphous, powder-like mass, of intensely bitter taste and a whitish colour, slightly bordering on yellow, somewhat hygroscopic, soluble in cold water, but more so in warm. It is equally soluble in alcohol, excepting the slight superabundance of carbonate of soda. On account of this great solubility it can be dispensed in all forms, and it is said to have done splendid service in the treatment of tenia and pin worms.

DR. J. BURDON SANDERSON ON INFECTION AND DISINFECTION.

NOTWITHSTANDING the multitudinous treatises that have been devoted to the subject of disinfection, each successive investigation seems to widen the field of research rather than to deal exhaustively and finally with any particular portion of it. Still some advance has been made, and a tendency is now evident to go beyond what Mr. SIMON calls "vague chemical libations and powderings" and to deal definitely with the specific organisms which are associated with different forms of contagious disease. Hitherto, attention has been mainly directed to the rendering of solid and liquid excreta innocuous, but in a memorandum appended to the Report of the Medical Officer to the Local Government Board that has been just issued, Dr. J. BURDON SANDERSON urges that this is not by any means all that can be accomplished by the application of chemical agents for the prevention of infective diseases. He points out that the innate no less than the extraneous contagia have a life history which is made up of two states of existence, alternating with or succeeding each other,—one in which they vegetate with more or less activity in the external environment, the other in which they have their abode in living blood or tissue, exerting there their hurtful function,—and that the problem of disinfection relates to the latter as well as to the former of these states. In the application of disinfectants, the attainment of one or both of two practical purposes may be kept in view: the direct action of the disinfectant on contagia so as to render them innocuous, or the arrest and inhibition of their morbific action within the body. Dr. SANDERSON considers that the most important lesson that has been learnt in recent researches respecting the nature of contagia is best expressed in the word "specificity," by which he means that each individual kind of contagium has a power peculiar to itself of producing a particular modification of the chemical processes which constitute the life of the organism it attacks. Very little is yet known respecting the effect of chemical agents upon the progress of such modifications within the organism, and before much extension of this knowledge can be hoped for not only will a more intimate acquaintance with the contagia be indispensable, but the nature of the modification produced by each will require to be worked out. Holding these views, therefore, Dr. SANDERSON indicates four lines of research which should be followed with a view of acquiring a better and more practical knowledge of the art of disinfection: (1) the disinfection of liquid and solid excreta and of clothing; (2) the disinfection of air; (3) the detection of contagia in food, air, or water; and (4) the use of colytic agents with a view to the inhibition of infective action within the living body. Postponing for the present a discussion of the first two divisions, he deals in the memorandum with the last two in some detail.

In attempting to determine the presence or absence of morbific germs in water or air the method of cultivation is the best available; but here we are met by a difficulty due to the universal presence of microphytes. Some assistance may be rendered by the analyst, but his results, as ordinarily obtained, do not help to discriminate between the living and non-living, much less between active and inert, between hurtful and innocuous. Dr. SANDERSON, therefore, argues that in the examination of water for the purposes of public health it is desirable to add to the approved methods of qualitative analysis a much more complete and systematic examination of its biological properties, which should have a point of departure in the qualitative sorting of the microphytes of contagium and aim at acquiring knowledge as to the morphological development of each species, as well as its external chemical relations with its environment.

In discussing the possibility of inhibiting the action of contagia after they have entered the human or animal organism, Dr. SANDERSON remarks that the knowledge we at present possess to assist us in attacking this part of the problem amounts to little more than that all contagia owe their power to their continued chemical action on the living substance of the organism they attack. In this and other points specific contagia resemble the common septic ferments, but they present marked points of difference. For instance, the symptoms of septic infection follow immediately on invasion of the septic poison and as rapidly subside, whilst the specific poison has a definite period of incubation and retains its hold upon the organism for a period equally definite, whilst both these periods, as well the pathological disturbance produced, are in general characteristic of the particular species. Agents antagonistic to septic infection before, as well as after, its entry into the organism are known, though little is understood as to the way in which they act, and the question arises whether similar agencies may not be discovered in relation to specific contagia. Dr. SANDERSON believes, for reasons given, that "all "contagious microphytes are related by descent to "the common microphyte of sepsis, and consequently "that whatever properties belong to the parent are "likely to be represented, more or less modified, n "those of the successors." Assuming, therefore, that the agent by which the septic microphyte produces its toxic effect is a ferment in the chemical sense, it might follow that the morbific action of the microphyte of small-pox is of the same nature; so that if it can be shown that septic fermentation is brought to a standstill by the development of an antagonistic chemical action, it seems possible that the mechanism by which the variolous fermentation is terminated is similar and within the reach of investigation. Recent researches have indeed shown that the development of microphytes in an albuminous fluid undergoing sepsis at a favourable temperature is a terminable process and that the period of the most active vegetation is coincident with the greatest toxical activity of the liquid. After this culmination the organisms cease to multiply, and eventually die, long before the nutritive material has been exhausted. This is regarded as the result of the interference of compounds resulting from the breaking up of the proteid molecules, which have been ascertained to belong to the aromatic group, and to be represented at an early stage in the septic process by acids of the acetic series, in which an atom of hydrogen is replaced by an aromatic molecule. One of these compounds so developed, phenyl-propionic acid, has been found by experiment to be more than twenty times as destructive of the vitality of microphytes as carbolic acid, and, therefore, one of the most powerful antiseptics known. Physiologists have long been familiar with the fact that chemical bodies of the aromatic group take part in the normal exchange of the material of the living body. It would seem, therefore, that no unimportant portion of the sanitary problem will be how best to maintain their presence in such relation to the body as to furnish it with the means of struggling against hostile agencies.

APOTHECARIES AND THE MEDICAL BILL.

In a recent editorial article in the *Medical Times, à propos* of the attitude taken by the Society of Apothecaries towards the Medical Bill now before Parliament, some views are put forward that recall a suggestion made a few years since by the first President of the Medical Defence Association, as to a method for settling satisfactorily what he termed "the counter practice controversy." Our contemporary is strongly adverse to the amendment of the Bill so as to maintain the Society of Apothecaries in the anomalous position it has so long held; but it professes to see a great future for that body if the rulers of it will only accommodate their course to the necessities of the time. It is of opinion that should the Medical Bill pass without any tangible modification, there would be a great likelihood that before the law has been in operation many years an irresistible demand would arise for a lower grade of medical practitioners, who would not think it beneath their dignity to accept the only fees that the labouring classes can afford to pay. Medical men, it says, are even now above the position which many of them have to take, so that there is a danger that when the law demands a still more prolonged and costly education, the poorer sick "will be entirely deserted by the doctors and left to the tender and ignorant mercies of the herbalist and prescribing chemist." When this crisis arrives, it is predicted, the public will demand that chemists shall receive some smattering of medical education, and be allowed to visit patients and treat them, or else that a lower grade of medical practitioners shall be created for the service of the poor. Already it is pointed out the State has recognized this principle of a lower grade of practitioners in the institution of the Dentists' Register.

In this emergency, according to our contemporary, the Government will naturally turn to the Society of Apothecaries, or the Pharmaceutical Society, as the proper authority for controlling the new departure. Or, adopting a suggestion made recently by a writer in *Blackwood's Magazine*, the two societies might form an alliance for the examination and authorization of low priced practitioners, in which case, it is thought, the Society of Apothecaries would have a fair claim to control the examinations. That Society is, therefore, recommended to give up its hopeless attempt at rivalry with the Colleges of Surgeons and Physicians and be content to take a lower place, the recompense suggested being the opening up of a useful and lucrative *rôle* for it in the not far distant future.

We have thus briefly paraphrased the principal points in the article in the *Medical Times*, rather because it may interest our readers to become acquainted with the views advocated seriously by so respected a contemporary than because we think they are likely at present to be included within the range of practical politics. It is not, indeed, for us to say whether the Society of Apothecaries will be tempted by the prospect of a "useful and lucrative *rôle*" to ignore its ambitious past, "get over the old idea . . . that a doctor must of necessity be a gentleman," and busy itself in opening up a "very useful and excellent career . . . for many of the picked pupils of the Board Schools." Nevertheless, we think such a course very unlikely to be adopted. But we believe our contemporary evinces profound ignorance of the sentiments of the chemists and druggists in this country as a body to suppose that they would voluntarily enter into any alliance which would place their examinations or any part of their proceedings to any extent under the control of a medical corporation. Such a proposition requires only to be mentioned to be stigmatized at once as likely to be fertile in misunderstanding and mischief. Moreover, we are convinced that such an alliance would be inimical to the best interests of pharmacy, if not of medicine. The scientific practice of pharmacy has a future of its own in this country and will be bes able to serve medicine whilst carried on independently of it. We have the past history of the Society of Apothecaries to show the effect of attempting to combine in one person the compounder of drugs and a low grade of medical practitioners. Naturally, this hybridism resulted in an undue predominence of what was assumed to be the higher—and probably was the most remunerative—strain in it, and the word "apothecary" acquired a new and non-natural meaning in the English language. We do not fear, therefore, that the Pharmaceutical Society of Great Britain will risk a repetition of this experience, and by taking a similar course promote a return to the dark ages of pharmacy in Great Britain, or be tempted under any such pretext to endanger the advance in pharmaceutical science which it has done so much during the last forty years to promote.

The Medical Acts Amendment Bill was the third order of the day in the evening sitting of the House of Commons on Friday, but at the time of going to press this stage had not been reached.

* * *

After six years' agitation the New York State Pharmaceutical Association has secured fresh legislation regulating the practice of pharmacy in all the counties of the State, except New York, Erie and Kings. The new Act practically places the duty of carrying out the examination, registration and supervision in the hands of a Board of Pharmacy, consisting of five members, who are to be selected by the Governor of the State from ten pharmacists nominated by the State Pharmaceutical Association. The Board will hold office for five years, the Governor selecting from nominees once a year the number of pharmacists requisite to fill up any vacancies that may occur.

* * *

The pharmacists of New York City, however, appear to have been less successful in an attempt to carry through the Legislature a Bill to confine the sale of drugs and patent medicines in the city to pharmacists. The Bill is said to have been defeated mainly through the influence of the patent medicine manufacturers, who through their counsel urged upon the Committee which had it under consideration that there is no responsibility attending the sale of patent medicines, and that many of them "possess no merit whatever" and could do no injury to the public!

* * *

At a recent meeting of the Paris Société de Pharmacie the subject of an International Pharmacopœia was broached by M. Petit, who suggested the advisability of having the draft already drawn up by the Society printed, and of remitting the consideration of the subject to a new Commission, the powers of the former one having expired. M. Ferrand objected that the impression produced upon him respecting this question whilst attending the International Pharmaceutical Congress in London was unfavourable to the initiative being taken by France, and M. Desnoix expressed an opinion that it would be better to await the decisions at the coming International Congress in Brussels before taking any further steps. After some further discussion it was decided that the manuscript should be communicated to the Brussels Congress.

* * *

Some of the friends and admirers of Dr. A. W. Hofmann in the United States, wishing to testify their appreciation of the services he has rendered to the world by his labours in chemical science and of commemorating his recent visit to that country, have subscribed to have a gold medal struck at the United States Mint in Philadelphia, and this has been forwarded with a complimentary letter to the learned Professor in Berlin. In acknowledging the receipt of the present, Dr. Hofmann, whilst modestly protesting that he has rendered no service which deserves such commemoration, and confessing that he is "somewhat perplexed by the monumental form" which the good feeling of his American friends has taken, expresses himself as deeply touched and feeling highly honoured by the solid and permanent token of their sympathy.

* * *

The Royal Society of New South Wales, with a view of encouraging original research, has published an offer to present a medal and a money prize of £25 for the best communication upon each of eight subjects which are arranged in three series. Among these subjects may be mentioned the "Influence of the Australian Climate in producing Modifications of Disease," to be sent in to the Honorary Secretaries, Sydney, not later than September 30, 1884; "The Chemical Composition of the Products from the so-called Kerosene Shale of New South Wales," to be sent in not later than May 1, 1885; and "The Chemistry of the Australian Gums and Resins," to be sent in not later than May 1, 1886. The competition is to be an open one and will not be confined to residents in the colony. A communication to be successful must be either wholly or in part the result of original observation or research on the part of the contributor, as no award will be made for a mere compilation, however meritorious.

* * *

We have received from Mr. J. E. Ryder, of Great Portland Street, a letter of warning that the "chloroform dipsomaniac" who a few years ago caused a considerable amount of annoyance and anxiety to several West-end pharmacists, by obtaining, under the pretence that he was a medical man a supply of chloroform and drinking it in the shop, has recommenced his mischievous operations. The man may be easily recognized by the fact that, apparently in consequence of some defect, he carries one arm folded across the chest.

* * *

A meeting of the London Section of the Society of Chemical Industry will be held in the Chemical Society's Rooms, Burlington House, on Monday next, at 8 p.m., when Mr. W. S. Squire will read a paper on "The Processes concerned in the Conversion of Starch into Alcohol, and their relation to Brewing and Distilling."

* * *

A meeting of the School of Pharmacy Students Association will be held on Thursday, June 12, at 8 p.m., when a paper will be read by the Honorary Secretary (Mr. Wyndham Dunstan), on "The Separation of Chlorides, Bromides and Iodides," and a Report on Practical Pharmacy will be made by Mr. R. A. Cripps.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, June 4, 1884.

Present—Messrs. Andrews, Atkins, Borland, Bottle, Butt, Carteighe, Churchill, Gostling, Greenish, Hills, Radley, Richardson, Robbins, Savage, Squire, Symes, Williams and Young.

The chair having been taken by Mr. Michael Carteighe, the minutes of the meetings of May 7 and 21 were read and confirmed.

The late Mr. Squire.

Mr. Carteighe read a letter from Mrs. Squire thanking the Council for the resolution passed at the last meeting.

Election of President.

A ballot having been taken in the usual way—

MR.. MICHAEL CARTEIGHE

was unanimously re-elected President for the ensuing year.

The President said he was extremely grateful to his fellow Councillors for this mark of their confidence. It was a source of satisfaction to find that his efforts in behalf of the Society had received their cordial sympathy and support. He could only say that whatever he had been able to do for the Society and the Council was largely due to the loyal support he received from every one of his colleagues.

Election of Vice-President.

On a ballot being taken—

MR. SAMUEL RALPH ATKINS

was re-elected Vice-President for the ensuing year.

The Vice-President expressed his acknowledgments for the honour conferred on him, and thanked his colleagues for the courtesy and sympathy which had been shown him during his previous terms of office. He said he would endeavour to devote the same amount of attention to the Society as he had done in the past.

Election of the Treasurer.

On a ballot being taken—

MR. JOHN ROBBINS

was also re-elected Treasurer for the ensuing year.

The Treasurer, in thanking the Council for the honour again conferred upon him, said that by the wise decision of the Council to re-invest its funds and securities with more advantage, the Treasurer during the past year had had to draw larger sums of money than any of his predecessors, and in the forthcoming year he would probably have to draw larger sums than would fall to the lot of any of his successors. As he had always taken an interest in the line of policy adopted he felt great satisfaction that it was being carried out during his term of office.

Standing Orders.

The Standing Orders of the Council were unanimously adopted for the ensuing year.

Letter of Resignation from Mr. Hampson.

The President read the following letter which he had received from Mr. Hampson:—

"205, St. John Street Road, E.C.,
"*June 2nd*, 1884.

"Dear Mr. President,—With feelings of regret I beg to resign my seat at the Council of the Pharmaceutical Society.

"In consequence of the continued illness of my wife and my own imperfect health, it is necessary that I should relieve myself of all unimperative duties, so that I may be able to obtain more leisure.

"My interest in pharmaceutical progress and in the welfare of the Pharmaceutical Society is unabated, and, perhaps, I may at some future time have opportunities of giving effect to this feeling.

"Kindly convey to the Members of the Council the assurance of my most friendly regard.

"I am, dear Mr. President,
"Yours sincerely,
"Robt. Hampson."

The Council went into committee to consider the letter, and the following resolution was passed unanimously on the motion of the President:—

"That Mr. Hampson's letter be received and entered on the minutes; that the Council, having in view the able services so long rendered to the Society, hesitates to accept his resignation, and instructs the Secretary to write to him requesting him to reconsider his determination."

Election of Secretary.

The President read the following letter from Mr. Elias Bremridge:—

"New Malden, Surrey,
"*May 31st*, 1884.

"My dear Mr. President,—In preparing the Agenda for the June Council Meeting, when the appointment of officers for the ensuing year will be considered, I have been reminded of the pleasure it has always afforded me on similar occasions to find that I continued to possess the confidence of the Council, as shown by my being unanimously re-elected. This has occurred year after year for a period of nearly twenty-eight years, and during the whole of that time it has been my privilege and my happiness to enjoy, I believe, the personal friendship of every member of the Council.

"I feel, however, that the time has at length arrived when it is desirable, and perhaps opportune, that I should request the Council to release me from my official duties as soon as may be found convenient.

"The growing necessity for this step has been on my mind for some time past, but it has required no small effort to screw myself up to make this communication and to ask you, my dear Sir, to make this announcement of my views to the Council at its next meeting.

"The reason that has had the most weight with me in coming to this conclusion is that my sense of hearing has become imperfect, and I find it is getting increasingly defective, so that, although the Council and the Committees have generously borne with this infirmity, the knowledge that I could only imperfectly perform my duties has, at times, been a source of depression and grief to me; moreover, I have recently had strong indications that I no longer possess my former elasticity and endurance.

"Under all these circumstances I could not conscientiously desire to retain my official position. But I shall continue to watch the proceedings of the Council with unabated interest, and I shall ever remember, with grateful feelings, the many happy years during which I have had the distinguished honour of carrying out its instructions and the important duties ordinarily devolving on the Secretary and Registrar.

"I beg to remain,
"My dear Mr. President,
"Ever faithfully yours,
"Elias Bremridge."

The President said this letter would be received with a general feeling of regret, but coupled with that the members of Council must entertain considerable respect for the courage which an old and valued officer showed by sending in his resignation when he felt he could no longer do the work as efficiently as he did in days gone by. He thought this was not the proper time to refer to Mr. Bremridge's great services and devotion to the Society. He should ask the Council to formally refer the letter to the Library Committee for consideration and report as to the best mode of dealing with it and filling up the vacant office, and the members of Council would have an opportunity of expressing their sentiments when the report came up.

The VICE-PRESIDENT seconded the motion, which was carried unanimously.

Mr. ELIAS BREMRIDGE was then unanimously appointed Secretary and Registrar until further notice.

ASSISTANT SECRETARY AND DEPUTY REGISTRAR.

Mr. RICHARD BREMRIDGE was also unanimously appointed Assistant Secretary and Deputy Registrar until further notice.

APPOINTMENT OF AN EXAMINER.

The PRESIDENT said the next business was to appoint an Examiner for England and Wales, in place of Mr. H. B. Brady, F.R.S., who had resigned.

The Council went into committee to discuss the merits of several gentlemen whose names were mentioned.

On resuming—

MR. W. H. SYMONS, of 2, Queen's Terrace, St. John's Wood,

was appointed, subject to the approval of the Privy Council.

APPOINTMENT OF EDITOR AND SUB-EDITOR OF THE JOURNAL.

Dr. B. H. PAUL was appointed Editor, and Mr. F. PASSMORE Sub-Editor of the Society's Journal for the ensuing year.

APPOINTMENT OF CURATOR.

Mr. E. M. HOLMES was appointed Curator for the ensuing year.

TREASURER TO THE SOCIETY IN SCOTLAND.

Mr. JOHN B. STEPHENSON was unanimously re-elected Treasurer to the Society in Scotland.

SECRETARY TO THE SOCIETY IN SCOTLAND.

Mr. PETER MACEWAN was re-appointed Secretary to the Society in Scotland.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Benjamin Henley Eastes, Loughton, Essex.
William Pierpoint Lawrence, 194, Great College Street, Camden Town, N.W.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemist.

William Pierpoint Lawrence, of London, a Pharmaceutical Chemist, having tendered his subscription for the current year, was elected a "Member" of the Society.

Chemist and Druggist.

Adam McGregor, of Ayr, who was registered as having been in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Bartle, William Frederick ......Greenwich.
Burchell, Robert Henry ....Kettering.
Oldershaw, George ....Liverpool.

ASSOCIATES.

The following, having passed their respective examinations and tendered (or paid as "Apprentices or Students") their subscriptions for the current year, were elected "Associates" of the Society:—

John, Benjamin ....Narberth.
Moss, Thomas Abbot ....Carlisle.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Acton, Frederick George ......Worcester.
Allin, Charles James ....St. Albans.
Barclay, John ....Birmingham.
Evans, John Richard ....Dowlais.
Farquharson, Alexr. McDonald.Aberdeen.
Flower, Walter.....................Barton-on-Humber.
Hitchman, Walter ....Kettering.
Jaques, George.....................Leeds.
Jarvis, James Henry ....Hastings.
Jones, Ebenezer Owen ....Swansea.
Lewis, Daniel ....Tredegar.
Menhinick, Chas. Hy. Foott ...Stonehouse.
Mould, Arthur H. .. ..London.
Owen, Alfred Ernest ....Newcastle.
Pearson, Ernest ....Cromford.
Puckey, William ....Bishops Stortford.
Smith, Henry ....Durham.
Tomkins, William Kingston ...Oxford.
Wisker, Robert Hardy ....York.
Withers, Herbert Percival......Penwortham.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

LOCAL SECRETARIES.

The nomination of Local Secretaries for the ensuing year was deferred to next month, in order that the list might be considered by the Library, Museum and Laboratory Committee. The following return was laid on the table by the Secretary:—

No. of towns eligible, 1883-4	305
No. of towns from which votes have been received	195
No. of towns from which no votes have been received	111
No. of towns added to the list as eligible (Accrington, Helensburgh, Maidenhead, Ruthin)	4
No. of towns removed from the list as not eligible (Exmouth, Redditch, Slough) .	3
No. of towns eligible, 1884-85	306

ADDITIONS TO THE REGISTER.

The Registrar reported that—

Francois Hippolyte Rebaute, of 26, Rue St. Gilles Paris; and

Richard Richardson, of Williamstown, near Melbourne, Australia,

having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been duly supported by qualified persons, their names had been placed on the Register.

An appeal against the Registrar's decision which had been made by a person who claimed to be registered was submitted to the Council and referred to the General Purposes Committee.

APPOINTMENT OF COMMITTEES.

The following gentlemen were appointed on the various committees for the ensuing year:—

General Purposes.—The whole Council. To meet at six o'clock on the evening previous to the Council meeting.

Finance.—Messrs. Gostling, Hills, Radley, Savage

Schacht, Symes and Woolley. To meet at four o'clock on the day previous to the Council meeting.

Library, Museum, Laboratory and House. — Messrs. Andrews, Bottle, Butt, Greenish, Hills, Robbins, Schacht and Squire. To meet on the second Wednesday in the month at eleven o'clock, except in August and September.

Benevolent Fund.—Messrs. Andrews, Borland, Bottle, Butt, Churchill, Greenish, Richardson, Robbins, Squire, Williams and Young. To meet at half-past three on the day preceding the Council meeting.

Law and Parliamentary. — Messrs. Bottle, Butt, Greenish, Hills, Richardson, Robbins, Squire, Symes, Woolley and Young. To meet as occasion may require.

Evening Meetings.—The Professors, the Editor and the Curator. To meet when required.

Freehold Investments.—The President, the Vice-President, the Treasurer, and Mr. Butt. To meet as occasion may require.

Revision of Bye-laws Committee.—Messrs. Bottle, Butt, Hills, Robbins, Schacht, Symes, Woolley and Young.

Spurious and Worthless Drugs. — Messrs. Greenish, Richardson, Symes, Williams, Woolley and Young; with Mr. Fred Barron, Mr. Richard B. Barron, Professor Bentley, Mr. Thomas Farries, Mr. G. Bult Francis, Mr. J. B. Herring, Mr. A. B. Hill, Mr. W. Hodgkinson, Mr. Holmes, Mr. E. Horner, Dr. Paul, Mr. Umney, and Mr. F. Yates, with power to add to their number. To meet when required.

The President and Vice-President are *ex officio* members of all committees.

Some conversation took place with reference to the appointment of the Committee on Spurious and Worthless Drugs.

Mr. WILLIAMS remarked on the fact of a large quantity of spurious cubebs having been recently offered for sale.

Mr. GREENISH referred to another case which had been mentioned in which nux vomica seeds had been mixed with ginger.

Mr. WILLIAMS said he understood the Committee had held no meetings during the past year.

The PRESIDENT said the object with which the Committee was originally appointed was to have a body representing both the Society and the wholesale houses, who would take notice of these matters. If anyone brought any special case under his notice he would call the Committee together at once. Part of the object no doubt was to consider any proposed legislation on the subject. It would not be wise to meddle too much with commercial affairs in the city.

Mr. GREENISH suggested that it would be a very good thing if a record were kept of cases of adulteration which were discovered, and tabulated. Such information would be very valuable in case any legislation were contemplated.

The PRESIDENT said this suggestion was worthy of consideration, and he would bear it in mind.

FINANCE.

Messrs. Carteighe, Atkins, Gostling, Hills and Savage, acting as an interim Finance Committee, had examined the accounts, and recommended certain accounts for payment. Their report and recommendations were received and adopted. These included the expenses of the Conversazione.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
April	Day	458	29	9	20
	Evening	128	10	3	6

Circulation of books.	Town.	Country.	Total.
	No. of Entries.		
April	168	117	285

Carriage paid, £2 4*s*. 3*d*.

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Report on the Progress and Condition of the Royal Gardens at Kew, during the year 1882. From the DIRECTOR.

Statements of W. T. G. Morton on his claim to the discovery of the anæsthetic properties of ether; Report vindicating the right of C. T. Jackson to the discovery, etc., 1853.

City of Boston, Annual report of the Inspector of Vinegar, 1884. From Dr. B. F. DAVENPORT.

Flückiger (F. A.), Grundriss der Pharmakognosie, 1884.

— Indische Pharmakognosie, 1884. From the AUTHOR.

Bentley (R.), Student's Guide to Systematic Botany, 1884. From the AUTHOR.

The Committee recommended the purchase of the undermentioned works:—

Keith Johnston's Atlas of Physical Geography,

Wanklyn and Chapman, Water-analysis, 6th ed., 1884.

Ramsay (W.), Experimental Proofs of Chemical Theory for Beginners, 1884.

Bentley (R.), Student's Guide to Systematic Botany, 1884.

Henfrey (A.), Elementary Course of Botany, 4th ed.

The Librarian having announced the need of more shelf room, it had been arranged that the President should consider how increased accommodation could be provided, and report to the Committee.

The Committee had ordered that the Library and Museum should be closed in the evening of Wednesday, May 21, and on Whit Monday, June 2.

The Committee recommended that sundry numbers of the *Pharmaceutical Journal* required by the Chemical Society to complete a set should be supplied.

Curator's Report.

The Curator had reported the attendance in the Museum during April to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	500	38	15	20
Evening	134	11	3	7

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

A series of herbarium specimens of Natal plants. From Mr. J. MEDLEY WOOD, Curator of the Botanical Gardens, Durban, Natal.

Specimens of perfect crystals of Arragonite and Quartz. From Professor LEON SOUBEIRAN

A series of herbarium specimens of rare medicinal plants. From Mr. THOS. HANBURY.

The Professors had attended and reported satisfactorily of their respective classes.

The late Mr. Peter Squire.

The report also referred to some correspondence with Dr. Balmanno Squire relative to his desire to found a prize in connection with the Society to perpetuate the memory of his father, Mr. Peter Squire.

Certain books had been ordered to be sent to the Library in Scotland.

The report and recommendations were received and adopted.

BENEVOLENT FUND.

The report of several members of Council, who had acted as an interim committee, and examined the applications for relief sent in to the Benevolent Fund Committee, was read. The report included a recommendation of the following grants:—

£5 to a life member, since 1864, aged 47. Many years in business, but now out of employment, having eight children, seven of whom are dependent on him. Surrey.

£10 10*s*. towards securing the election of an orphan girl, to the British Orphan Asylum, to be expended at the discretion of the Secretary. Sussex.

£5 to the widow of an associate, aged 54, suffering from ill health, and with an invalid daughter. Applicant has had six previous grants. Middlesex.

£15 to the widow, aged 56, of a registered chemist and druggist, and member of the Society for fourteen years. Applicant has had three previous grants. Northampton.

Some cases had been deferred for further inquiries, and some the Committee had declined to entertain.

The following letter had been received by the Secretary from Mr. W. H. Baigent, of Shefford, Bedfordshire, who last month presented a hundred guineas to the Fund:—

"*May* 14, 1884.

"My dear Sir,—After seeing you on Monday it occurred to me that perhaps the Council might be disposed to entertain the subject of augmentation of the pensions, in the first place taking the higher grade and gradually increasing the pensions to £50 per annum, with this proviso, that the annuitants be founders, pharmaceutical chemists, or subscribers to the Benevolent Fund for more than six years, and also that their income from all sources shall not exceed £40 per annum.

"I have lately had under my notice several who in former years have held higher positions but are now reduced to seek help from our pension fund.

"I think if this plan could be entertained it would cause many more to subscribe to the Benevolent Fund, and establish a social feeling in the Society which might bear some good fruit.

"Yours truly,

"Elias Bremridge, Esq. "W. H. Baigent."

The Vice-President, in moving the adoption of this report, said Mr. Baigent's proposal had received the earnest attention of the Committee, but, on the suggestion of Mr. Bottle, it had been decided to ask the office to furnish information as to what number of persons would be affected by the proposal. The impression of the Committee was that the number would be very small, so that even if the suggestion were adopted it would not make much difference financially; but if the figures should show, on the contrary, that a large number would be eligible for receiving the increased grants, he should personally feel bound to oppose it. His feeling was that it was a much greater gain every way to give a smaller sum to a greater number of people than to advance the comfort of a restricted number. When he thought of the large number of applicants who were kept back for want of funds, and the value which even £30 year was in saving persons from absolute destitution, he thought the Council should go in for extension of the area of relief, rather than increase of the amount. One other point had been mentioned to which he should like to call attention. The desire of the Committee was that the influence of the local secretaries should be more largely made use of in aid of the Benevolent Fund, and one suggestion made was that all the action of the office with regard to particular cases should go through the local secretary; that instead of sending out forms of application to the applicant, they should be sent through the local secretary who would thus form the medium of communication with the office. It seemed to him that that would be imposing an unnecessary burden on the local secretaries, and he feared it would rather interfere with instead of facilitating applications. The Committee did not very favourably receive the suggestion, but were quite unanimous in recommending that whenever the information supplied was in any way defective the local secretary should be at once communicated with and asked to furnish additional information.

Mr. Robbins said the question raised by Mr. Baigent's letter was most important, but he did not know that his suggestion was the best which could be made. He rather thought that a plan which he himself suggested some time ago would be preferable, and which he still believed would prove of great advantage to the Fund, viz., that every annuitant who had formerly subscribed twenty guineas to the Fund should be entitled to £50 a year, and those who had subscribed ten guineas to £40 a year. After giving a great deal of consideration to this question he had come to the conclusion that such a plan would be of great service to those who had formerly moved in a good position in society, and had been unfortunate, but to whom £30 a year was a miserable pittance, and was just the same amount as was given to those who had never contributed anything to the Society, and had never moved in the same position of life. From another point of view he thought it would be advantageous, for if it were known that by subscribing a certain amount persons would receive a larger income if reverses came, there would be a much greater number of subscribers than at present, and thus a large addition would be made to the Fund, whilst at the same time very few of the subscribers to the amounts named might ever be expected to become applicants for relief. Very few, comparatively, who had subscribed to the Fund had ever applied for its benefits, and he believed only one who had subscribed ten guineas.

The President said these remarks would be more appropriate at the next meeting, when the Committee would have probably made a report after having considered the statistics which the office would furnish.

Mr. Symes observed that on Mr. Robbins' own showing those who subscribed were never likely to want assistance from the Fund, and, therefore, he could not see that the motive held out would have much operation. This proposition was something in the nature of a mutual insurance fund, but as a benevolent fund scheme he thought it was altogether impracticable.

Mr. Robbins said several cases had come under his notice in which he was very sorry that the Council had not the power of giving more.

Mr. Bottle said he did not propose to follow up the discussion on this letter, because it would be premature to do so at the present time; but he wished to correct a little misapprehension which the Vice-President had evidently fallen into as to the suggestion he had made to the Committee. His idea was that without waiting for the Committee to meet and consider the applications, the office should, immediately on receipt of an application, communicate with the local secretary and obtain all information possible with regard to the case, so that it might all come before the Committee at the same moment.

The President, in corroboration of what had been said by Mr. Symes, thought Mr. Robbins rather mistook the object of the Fund when he made the proposal to which he had now referred, and which he had brought forward from time to time. The Fund was a benevolent fund, and he could recognize no difference between the case of a man who had been in receipt of £5000 a year, and one who had only had £100 a year all his life, when he came to ask for assistance. It was contrary to the true spirit of benevolence and to the catholicity of charity to make any artificial distinction between one man and another. If Mr. Robbins were very enthusiastic about this scheme it was open to him to suggest the foundation of a Mutual Insurance Fund, such as was actually in contemplation among the medical profession at the present moment; but on the lines on which the Benevolent Fund was constituted the Council could not touch that question, or graft a mutual insurance scheme upon a benevolent fund. Moreover, it would spoil one of the greatest gifts the Society had ever conferred upon the trade, which was effected when, by the Act of 1868, the benefits of the Benevolent Fund were thrown open to all persons upon the Register, whether connected with the Society or not.

Mr. Robbins said he did not recommend a mutual insurance scheme.

The President said it came to very much the same thing. The Fund was essentially one for the relief of distress, and if it were desirable to give £50 a year to anyone of a certain age, it was desirable to give it to everyone who presented proper credentials.

The report and recommendations were then received and adopted, and an additional grant of £10 for the support of two of the Isherwood orphans was also made, the application for the usual quarterly payment having been received that morning.

The Inaugural Address in October.

It was resolved that the Library, Museum and Laboratory Committee be authorized to make arrangements for the delivery of this address.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The thirteenth general meeting was held at the Royal Institution, on Thursday, April 24. The President, Mr. E. Davies in the chair. The minutes of the previous meeting were read and confirmed, and the following donations to the library were announced:—The *Pharmaceutical Journal*, from the Society; the *Canadian Pharmaceutical Journal*, from the Editor; the *Science Monthly*, from the Editor.

In the absence of the Secretary, Mr. A. C. Abraham read the following paper, entitled—

Suggestions upon the Preparation of Lard.

BY F. A. BROWN.

In the short paper which I have written, I shall endeavour to show that lard can be prepared on a small scale, easily, cheaply and reliably.

No doubt from its being so largely used by pharmacists, its preparation has not received that amount of attention it requires. I believe (in fact, I am certain) there are a great many retail chemists who buy their lard from pork butchers or provision merchants by the bladder, or else what they term "home rendered."

A few years ago, I was persuaded by a tradesman to try some of his "home rendered," which I was assured was beautiful, as it had been specially rendered. To all appearances it seemed a good sample. With this I prepared some zinc ointment as an experiment; in less than a week I had to throw it away as the smell from it was abominable.

No doubt the bladder lard is the most reliable that can be bought from the class of tradespeople I have mentioned. My advice is, do not buy lard; prepare your own, but not according to the B.P. process.

The first thing to be done is to procure some good flare from a reliable source; choose the thickest you can get, and when you can, from a pig that has been fed with good food. Having obtained what you consider a good piece, hang it up freely exposed to light and air for a week or ten days, then proceed as follows:—Cut away as much of the membrane as possible, then beat it well in a mortar (which will cause the fat to melt at a lower temperature), melt over a water-bath, taking special care that the temperature does not exceed 130° F., strain through flannel; then you will have a beautiful white preparation of good consistency and free from smell.

The two chief points are having good flare and the temperature at which it is melted. If it has been well mashed, the fat can be melted at 110° F. By the experiments I made the amount of lard produced from the flare was 86 per cent.; the thicker the flare the greater the percentage. The directions in the B.P., "break up the masses of fat with the hands, exposing every part to the water," I think is a mistake, as it causes the lard to turn rancid. None of us would think of putting cod liver oil in wet bottles, therefore we should not let water come in contact with the broken-up fat.

Lard prepared by the process I have described will keep good in colour and free from smell for over twelve months, as will zinc ointment prepared with it. I have used it in making red and white precipitate ointments, using one ounce of white wax to each pound of lard in the summer months and rather less in the winter. I have found these to keep good in colour and free from rancidity for over three months. I think that is as long as they are required to keep good in most pharmacies.

A vote of thanks to Mr. Brown having been passed Mr. Davies delivered the following—

Valedictory Address.

It is my pleasant duty now to close the proceedings of the session with a few words of farewell. We have, I trust, usefully employed some of our winter evenings in imparting and receiving knowledge, and now the approach of summer calls us to the more appropriate study of nature herself, to learn our lessons from the ever open book which she spreads before us, and I hope to receive renewed physical vigour in the fresh air by the seashore. What lessons we may learn I hope we may be ready to impart, and that the summer may ripen a harvest on whose fruits we may feed next session.

It is usual to review the work of the session in the valedictory address, but I think you will scarcely thank me for a dry *résumé* of the papers read and the communications received. Rather would I in general terms express an opinion that we have had success quite equal to our expectation. Papers have come in to supply every evening, they have been varied in character, whilst they have all had a direct reference to the objects of the Association, and they have exhibited no inferiority to those of former sessions. Old members of the Association have shown that they have not forgotten us, though no longer in our ranks, whilst some who are still with us and on whose readiness to come forward we can always rely, have again paid the debt we owe them by increasing our indebtedness. Nor have we been without new recruits, who have broken through the trammels of fear and have made that first step which is to inaugurate a march along with the veterans of our army. Would that there were more like-minded, who would find that they may learn by teaching, and who will find no stern critics, but rather helpers and encouragers in their early endeavours.

Miscellaneous communications have been fairly numerous, and have given opportunities to those who shrink from a paper to impart the results of their investigations.

We have received donations of specimens, books, and journals, by which our Museum and Library have been enriched, and for these our grateful thanks have been tendered.

I am thankful to believe that death has not been busy in our ranks, but departure from Liverpool has removed some. Of these the most conspicuous was Mr. Mason, a personal friend of me and many, whose kindly help as Vice-President was extended to me in the discharge of the duties of the chair, who could always be trusted to for a paper, and whose fearless yet courteous discussion of the topics arising at our meetings tended to prevent us falling into the weakness of being a mutual admiration society. We must hope that our loss may be repaired by more energetic action on the part of those who remain, and by additions to our ranks from without. In this last respect I am sorry that this session has not added many to our ranks, but I trust that by the extended freedom and range of subjects now offered those who have fought shy of pure science will be attracted. I would even hope that the bane of Liverpool societies for the advancement of knowledge, that is, their excessive multiplication, may be attacked by us, and that those who study the same things in pharmaceutical matters may study them together. One of the oldest societies in Liverpool would then set an example to the rest, and so develop strength by concentration of effort.

In looking forward to the employments of the recess, I would strongly urge the study of botany. No science can beat it for dryness if studied from books alone, none for interest if studied from nature. Let every fact be verified by the student for himself; let the plant explain the terms, and it will be found that botany is not a vocabulary of Greek and Latin words, nor even the collection of more or less rare plants in a herbarium, but that it is the study of life in its most varied forms, that it is full of surprises in the adaptation of means to ends, and whilst neatness and skill are taught in the dissection needful, yet there is not that suspicion of cruelty which attaches to studies of animal life. If a student cannot get much into the country, yet in our market a constant supply of many wild flowers can be got, and over the water on Bidston Hill or Oxton Heath some rarities may yet be found in the compass of an evening walk.

I must now come to a conclusion. I have enjoyed my year of Presidentship from the kind assistance which has been extended to me, although it has entailed labour upon me I had at one time hoped to escape. If my efforts have been of any use, I have been amply rewarded, but it is on you that the success of the Association must depend. It is only by the willing co-operation of all that the Association can maintain its position, and I call upon all to lend their aid so that it may still rank among the societies of this city, which have for their object the raising of the minds of its citizens above the considerations of the mere mechanical routine of life, whilst that very routine is assisted and developed into intelligent and wisely directed work.

After the conclusion of this address the election of the President for the ensuing session was proceeded with, when Mr. E. Davies was unanimously re-elected President.

This concluded the business of the meeting.

Proceedings of Scientific Societies.

INTERNATIONAL HEALTH EXHIBITION.

On Wednesday last the first of a series of Conferences, which it is intended to hold in connection with the International Health Exhibition, took place in the arena of the Albert Hall, under the presidency of the Right Honourable the Lord Mayor. As many of the subjects announced to be discussed at these Conferences promise to be of interest to the readers of this Journal, we purpose as far as possible to give a weekly *résumé* of the proceedings.

The first paper read was by Mr. G. B. Longstaff, on "The Population of London and its Migrations." The author first referred shortly to the populations of some of the chief ancient cities as being large compared with most of the capitals of modern Europe. Similar reference was also made to other large cities of the present day, but, said the speaker, "such an agglomeration of human beings as is now living, toiling, suffering, pleasuring, entering the world and quitting it, in modern London is absolutely without precedent in ancient and modern civilization." London proper contains more people than Paris, Berlin, and Brussels together; and the greater London includes within the Metropolitan Police District has little short of five millions. A large and important city it had been since the Roman occupation, and Good Queen Bess thought it large enough, in 1580, when she forbade the erection of new buildings, as the extension of the Metropolis "was likely to increase the plague, to create trouble in governing such multitude, a dearth of victuals, the multiplying of beggars, the assemblage of more artizans than could live together, and, moreover, as likely to impoverish other cities for lack of inhabitants." But London was not yet grown up and was still growing at the rate of 50,000 a year, 1000 a week, or 150 a day! Statistics followed showing the increase of population and the birth and death rate in London as compared with other cities. With regard to immigration into London, it was somewhat surprising that Scotch, Irish, foreigners and colonists together only numbered some 6 per cent., but it must be borne in mind that their children were of course classed among the London born. Of the foreigners Germans were the most numerous, and next came French, Poles (mostly Jews and very poor), Dutch, and Italians. No great manufactures were carried on in London save in connection with furniture and books; and some interesting though voluminous figures were given of the persons following various occupations. The very poor class numbered 100,000, and there was a much larger number but very little removed above them. The speaker confessed himself a disciple of Queen Elizabeth, and wished something could be done, if not to diminish the number of inhabitants, at least to prevent their increase. Emigration was the only practicable remedy, but should not be promoted from London itself, merely, as for every family sent away from it two would rush in from the provinces, and even from Ireland, and country people made far better emigrants than townsmen. In fact, everything possible should be done to discourage immigration into large towns. With regard to the administration of London, the governments in the thirty-nine districts occupying twelve miles from north to south and seventeen from east to west, and supposed by common consent to be utterly incompetent, had, at all events, reduced the average death-rate to 22·5 per 100, which was much exceeded on the continent of Europe, as for instance, in Christiania, a mere village in comparison.

In the discussion that followed, Canon Gregory, referring to the "migrations of the people," said that when he was in Lambeth it was calculated everybody in the parish removed once a year; but they did not go far enough. Decent accommodation could be found for all if they could but be brought to the thousands of unoccupied houses in the suburbs, and the problem was, how was that to be brought about?

The second paper was read by Mr. Toynbee (for Miss Gertrude Toynbee), on the "Treatment of the London Poor." The writer argued that in addition to their material privations and sufferings the poor were almost entirely deprived of such friendship and social intercourse as other classes enjoyed, from the wretched character of their homes. In many houses with thirty or forty occupants scarcely a family had more that one room, the families consisting of father, mother, and sometimes as many as five children. Such places were not *homes*, and yet as much as 6*s*. a week was paid for them. The want of anything homelike in their dwellings was the key to much of the misery in the lives of the poor. Children especially suffered from it, and were thrust into vice, when with other surroundings they would become virtuous men and women. Many sanitary improvements were required in the dwellings of the poor, and at any rate efforts should be made to give the children some pure and bright experiences which would help to obliterate the evil in their minds. Purer recreation should be provided for old and young, men and women, in their leisure hours, week-days and Sundays, to enable them to forget the evils which could not yet be removed.

The Rev. A. Mearns followed with a paper on "Overcrowding." He said, though the urban average in England was six people to an acre, places existed where there were from six hundred to one thousand to one acre. Distressing details of overcrowding in poor neighbourhoods were given, and public improvements, high rents, and the necessity of men living near their work were mentioned as the chief causes. Its physical results were bad enough, being of course a fertile source of disease, but its moral effects were fearful to contemplate The registration and official inspection of all property let out in rooms would do much to remedy the evil, and under the Glasgow Police Act that system was at work with good results. Artizans' dwellings should be erected at rents which could be paid by the very poor, and on the authority of Miss Octavia Hill they would still yield a fair percentage upon the capital expended.

The second Conference on the "Dwellings of the Poor" was held under the auspices of the Mansion House Council, on Thursday, in the Royal Albert Hall. His Grace the Archbishop of Canterbury in the chair.

The first paper read was on "Suburban Dwellings and Cheap Railway Fares," by Mr. James Hole, who stated that the increase of the population of London was about 50,000 per annum, and that all the efforts of benevolence in the past twenty years would not provide the accommodation required by one year's increase. The exigencies of space in London proper only permitted of the block system for the growth of population, and he recommended the single dwelling outside London where the tenant could have a few yards of garden, breathe pure air and cultivate the home feeling such as he could never experience in buildings constructed like barracks. After referring to the labours of the Artizans' Dwellings Company, which had completed estates at Shaftesbury Park of about 1200 houses, and at Queen's Park, Harrow Road, of 2170 houses, and was now erecting 2600 houses at Noel Park, near Hornsey, the rentals of which ranged from 6*s.* to 11*s.* 6*d.* per week, Mr. Hole stated that one great benefit to the poor was that public houses were not permitted on these estates. To ensure the success of these schemes it was necessary that the railways should be induced to afford adequate facilities at reasonable rates, as the so-called workmen's trains did not meet the necessities of the case. He proposed the creation of a paid Government Dwellings Trust, with the necessary powers to carry out working class model towns, the funds of which should be derived by the issue of debentures; secondly, the contributions of the working classes in the repayment of the mortgages; and, thirdly, if the above was not found adequate, by a Government loan.

The second paper, by Miss Lidgett, was upon "The Treatment of the London Poor." After describing the horrible condition of the dwellings of the poor and the almost hopeless task of improving them, reference was made to the labours of Mr. Ruskin and Miss Octavia Hill to improve the dwellings of the poor, to the efforts made to teach the people how to keep them clean and how honestly to pay for them. This was not a matter of mere bricks and mortar, of plaster and whitewash, that could be ordered or inspected by public authority, but was a work that for the most part must be done by ladies.

The third paper was by Mr. H. D. Harrod, on "The Creation of a Building Fund," his opinion being that purely voluntary effort was insufficient to meet the exigencies of the case. There was a commercial and a philanthropic side to the problem which it was desirable to keep apart. A commercial company was hampered by the desire to make a dividend, and a large public trust was therefore in many ways preferable. Taking Mr. Shaw Lefevre's figures as a basis, land purchased by arbitration, without the compensation given under the Lands Clauses Act, would cost 8*s.* per foot, or £17,424 per acre. Dealing with forty-two acres, of which one half would be covered, the other half being left for roads and open spaces, the cost would be about two and a half millions. The rents should be 2*s.* 6*d.* a room or 4*s.* for two rooms; and on this basis the income would be £148,512, out of which, allowing two-fifths for expenses, repairs, etc., there would be a net income of £89,108, which would pay interest at 4 per cent. on nearly the whole capital, leaving but a small outlay to be made from the Trust fund. If half the amount required could be borrowed from the State at 3 or $3\frac{1}{2}$ per cent., there would be no difficulty. Such a scheme would provide for 47,140 persons. The Trust might also assist private enterprise in the same direction with loans of capital at moderate interest. In conclusion, the philanthropic side of the problem might be provided for by adopting Miss Octavia Hill's system of employing ladies as rent collectors, who would make friends of the tenants and help to raise their moral tone in every way.

The Chairman was glad that at last public attention had been called to a matter to which earnest labourers had been trying to call attention for forty years, for now they might expect some good to arise from the agitation. Ages ago the idea of a Greek or Roman city was that it should be compactly built, with very little knowledge indeed of sanitation, but with the proviso that all round about the walls there should be a great area of common land. Still it was almost too much to hope to have great rings of land around the villages and towns of England. It had been well suggested that great things might be done by enabling the working classes to own their own houses; but they knew, as practical people, that such a time would not come to pass, though to a certain extent it might be the case. Everyone would agree that it was not good for human beings to be in the hands of middlemen. Another question which seemed to be in a fair way of settlement springing out of the creation of rural villages was that of intemperance. He did not wish to be chimerical and to see the whole of the land covered by model dwellings, for he thought the artizans did not like living in model blocks; they preferred to live in houses or cottages which could be rendered tenantable. It must not be forgotten that the poor were human beings, and as birds and beasts liked to make their own nests and lairs, and as the most polished specimens of the human race spent perhaps a disproportionate time in beautifying their dwellings, as far as possible every working man should be allowed to have some kind of voice in buying his own house. All honour was due to those who, in the first instance, had attempted to deal with the subject. While many people starved the masses will hear those who associated with them generally took the kindest view abont them, and he fully agreed with what Miss Lidgett said about talking to the poor about religion. All men should remember that the poor were of the same flesh and blood as themselves, and if the rich would associate more with them and learn to love them England would be a much happier land than it had ever been.

Reviews.

A Treatise on Chemistry. By H. E. Roscoe, F.R.S. and C. Schorlemmer, F.R.S. Vol. III.; Organic Chemistry, Part II.*

We are glad to receive a further instalment of this valuable and comprehensive work on 'Chemistry.' In these days of little books and books to match the necessities of particular sets of students, or the demands of specified examinations, though many of them have their value, one welcomes the appearance of volumes which deal with their subject, be it chemistry or any other, with the sole object of producing what shall be at once a history of past successes, and by their clearness and completeness in detail lead on the student to that mastery which alone is the parent of discovery and so help him to future triumphs. For the genuine student who wants to know chemistry and not to "*get it up*" this is one of the best treatises ever written on the subject.

The part of Professors Roscoe and Schorlemmer's book which is now before us begins with an account of the divalent alcohol radicles, and their compounds and de-

* London: Macmillan and Co. 1884. Demy 8vo. Pp. i.-xii., 1-655. 21s.

rivatives, and includes the uric acid derivatives. the trivalent alcohol radicles. the univalent alcohol radicles of the C_nH_{2n-1} series; also the oleic acids, the $C_nH_{2n-1}(CO_2H)_3$ acids and those allied to them, the acetylene or ethine series of alcohol radicles, the drying oils, the alcohols of the quadrivalent and sexvalent radicles, the carbohydrates, the furfuryl group, and the meconic and tetrinic acid groups. In short, it brings us to the aromatic compounds, which we may look for in the next portion of the work.

As in the previous volumes these writings on chemistry are distinguished and their interest is heightened by their valuable historical details and the copious references to original sources of information, whilst we again find much attention given to important industries connected with the subject, such as sugar making and refining, and paper making, though from the nature of the case the space devoted to such matters is somewhat less than in some of the earlier volumes. We cannot, however, speak quite so well of the treatment they receive in this section as we could wish. For example, we are sorry to observe some elaborate illustrations quite unexplained, *e.g.*, figs. 126, 127 are referred to in the slightest manner. They would, no doubt, be clear enough as they stand to those technically acquainted with the subject already, who, however, do not need them; but to students, for whom we may presume they are intended, they will be of little value. Similarly the chapter on saccharimetry, though technically sufficient, perhaps, is, in an essentially scientific book like the present one, disappointing. On the other hand, the purely chemical portions, which comprise the vast majority of the book, are most valuable and will thoroughly maintain its high reputation. The general account of the ethene group, with which the volume opens, is extremely clear and will be found most valuable. There are misprints here and there, but they do not seem to be numerous.

In concluding our remarks, we cannot help expressing our wish that chemists would come to some agreement in the use of terms. In the book before us we find, for example, such expressions as "divalent or diatomic alcohol radicle." At present, no doubt, this is done in the interest of students who may be familiar with expressions on one or the other system only. In the long run, however, the difficulties of utilizing the study of chemistry as a method of training are greatly added to by the needless trouble given by having two or more names for one thing in so many cases. An eminent physiologist lately warned science teachers of the danger they are always in of ceasing to teach science and of teaching its dry bones, its terminology, instead. The difficulties of teachers of chemistry are already very great in this direction on account of the imperfections of its terminology, and we feel that it is to the writers of the leading text books that they must look for help in this matter, for in this they must follow the books.

THE STUDENT'S GUIDE TO SYSTEMATIC BOTANY. By ROBERT BENTLEY, F.L.S., M.R.C.S. Eng.*

This little work is intended to form a supplement to the 'Student's Guide to Structural, Morphological and Physiological Botany,' lately published by the same author. Systematic botany is often taught at a different time of year from structural botany, and the appearance of a small and very portable volume on the former subject, which can easily be carried in the breast-pocket, will be a boon to the class of students who have hitherto had to carry the 'Manual,' which, however valuable as a work of reference, is by no means convenient for out-door study. The author believes that the work now under consideration "will form a most convenient and handy little volume for use abroad and at home by medical, pharmaceutical and other students who are desirous of obtaining a good practical knowledge of some of the more important natural orders and their medicinal plants, and also as a foundation for further study." As a matter of fact, the author has condensed into this book the systematic portion of his Manual by omitting the portions relating to the uses and properties of the plants of the different natural orders, as well as the detailed accounts of economic plants, the description of the natural orders being thus compressed within one hundred and thirty-six pages. The remaining pages are devoted to descriptive botany, which includes two chapters, the first giving directions for examining and describing plants, and an explanation of the abbreviations and symbols used in doing so, and the second containing nineteen descriptions of medicinal plants at full length in illustration of the directions given in the first chapter.

This portion of the work will be found exceedingly useful to the student. The plants used as illustrations are most of them easily obtainable and belong to different natural orders, so that the student will find them to answer a double purpose, since they not only serve as models for describing plants, but as a key to explain many points that might prove puzzling to a beginner.

The systematic portion of the work possesses the advantage that it cannot possibly be used for "cramming" purposes. The only way to use it is to examine, book in hand, the different genera of each family, as far as obtainable, in a botanical garden, and even then probably the student will require the assistance of his professor to explain the value of such descriptions as "leaves alternate or opposite; corolla of 3 to 15 usually 5, distinct petals, regular or irregular, sometimes absent."

The long experience of the author in teaching botany has doubtless shown him that a thoroughly inclusive description is the best form in which the natural orders can be presented to students; but as a foundation for further study, one feels that it would be less puzzling to begin with something simpler, and that the relationship of the natural orders would be more easily remembered if they were accompanied with some hints such as are met with in works like Lindley's 'Natural System of Botany.'

Those, however, who are accustomed to the well-known Manual,—and they certainly form a considerable proportion of botanical students,—will gladly welcome the portable little volume now under review, and those who will take the trouble to thoroughly follow out the directions given under descriptive botany are not likely to fail in describing a plant at their examination, even if the specimen be one unknown to them.

DIE PARFUMERIE FABRICATION. Von Dr. chem. G. W. ASKINSON. With Twenty Illustrations. Second Edition.*

This little volume on the manufacture of perfumery is one of a valuable series of works on chemical industries by the same publisher, all of which are remarkable for the large amount of really valuable information condensed into a small space. The present volume is no exception to the rule. On turning to the list of contents, one is surprised to find that in three hundred and sixty-four pages, no less than thirty-one chapters are comprised, each of which contains thoroughly practical and useful information. The illustrations given are of apparatus, not of plants, and such information as can be readily obtained in works of materia medica, such as the preparation of the oils of lemon, bergamot and otto of rose, will be sought for in vain here; but instructions as to the quality, tests of purity, uses, etc., are found instead. The author, being himself a manufacturer of perfumery, has treated the subject from a business point of view. In the preface he states that the receipts which he has given are those which he has himself found to be valuable and that he prefers to give a few that are reliable rather than a number which he cannot honestly recommend.

The formulæ given seem to bear out his claim, the

* London: J. and A. Churchill. 1884. Fcap. 8vo. Pp. i.-xii., 1-178. 3*s.* 6*d.*

* Vienna: A. Hartleben. Crown 8vo. Pp. i.-iv., 1-383. 4 Mk. 50 Pf.

majority having sufficient of the staying element in them to produce powerful and lasting perfumes.

Besides receipts for perfumes for the handkerchief, the book contains others for smelling salts, toilet vinegars, pot pourri, pastilles, incense, cosmetics, perfumed pastes, powders and jellies, pomades, bandoline, tooth powders, finger nail powders, hair dyes, rouge, etc.; in fact, it embraces the whole range of the perfumer's art. The only drawback to the book is that it is printed in German type and that the whole of the information about any one perfume or oil cannot be found under one head. Those of our readers who understand German will find the book worth purchasing, if only for the recipes it contains, and those who do not will not have great difficulty in making out, with the aid of a dictionary, the names and proportions of the ingredients. If here and there a statement occurs such as that the root of opopanax has a pleasant odour, the trite saying *de gustibus non disputandum* may be called to mind. In this instance, moreover, the author honestly states that the opopanax perfume has a very different source.

THE ELECTION OF COUNCIL.

Sir,—It is at once a curious but interesting feature in the history of the contested elections for the Council of the Pharmaceutical Society, that between the years 1870–1881, there was always a vacancy to be filled up when the time for election of the new Council arrived. During the last four years, however, all the old members of Council have stood the contest and been returned, as a body; but it is nevertheless true that the majority is steadily decreasing, since in 1881 it was 448, in 1882, 336, in 1883, 281, and now it has fallen to 254.

One cannot but congratulate the successful candidates upon their re-election to the Board duties; but as one of the 1287 who took sufficient interest in the affairs of the Society to return their voting papers, I trust the remarks in your leading article of last week will direct the attention of the Council to the urgent necessity of adopting some means of eliciting the sympathy and interest of the remaining 2385 to whom voting papers were issued.

Such a vast proportion of apparently disinterested members (the largest, I believe, since 1876) should at least raise the question, Are there sufficient local secretaries? Are they encouraged to interest country members in matters relating to the Society's welfare? or are they only a collecting medium for picking up the annual guinea from defaulting members?

Would it not be wise, would it not be a gracious act for the Council to encourage the furnishing of reports by the local secretaries, whereby the governing body might become better acquainted with the state of trade generally and the requirements arising from different conditions in the smaller towns, where, indeed, the health of pharmacy is just as much to be advised as in the large centres of industry and wealth? Such means would, I believe, be fraught with most beneficial results, since it could not fail to impress upon our minds that the work of our Council for legislative and pharmaceutical reform would then be better guided for the benefit of the whole body of chemists.

11, *Strand, Torquay*. CHAS. SHAPLEY.

NOTICES TO OFFENDERS.

Sir,—The President, in his address at the Annual Meeting, referred to what to him appeared the mistaken view of some members, in thinking that no letter of warning should be sent to offenders against the Pharmacy Act previous to proceedings being taken. As an ordinary member I hardly like to differ from so high an authority, but it is evident I am not alone in my views. It is a most courteous and honourable way of carrying out the Act, and doubtless offenders fully appreciate it, but I very much question its policy. It is, I believe, generally known that trading in poisons by others than chemists is illegal, else why should there be such an expression of surprise that poisons are so readily obtainable at almost every inquest on what may be termed "illegal cases of poisoning?" Besides which ignorance of the law is never admitted in other cases as an excuse for non-compliance with it.

It seems to me that we are treating others in a way that we should not expect to be treated ourselves. If a chemist sells methylated spirit without a licence, I do not think the Revenue Authorities give him notice before proceeding against him, and I doubt very much if the Treasury would entertain any application for a remission of the penalty, and to take a more extreme case, if a chemist poisons a customer it is not very probable that he would receive a letter warning him not to do it again or else proceedings would be taken against him. If traders know that they will be warned they feel perfectly safe until they receive that warning, naturally omitting to use any labels whatever, in order not to attract notice and so postpone the receipt of the warning as long as possible.

To my mind it appears that we are neglecting our duty in not stringently carrying out the provisions of the present Act, and in the present state of the public mind I do not see that we are justified in asking for further powers when we do not use those we possess to their fullest extent. If there is any hardship in enforcing the law, the responsibility rests with those who made it, not with those who have to carry it into effect. For the public good we are entrusted with this duty, and we have no right to condone any offence on the promise of better behaviour in the future. We are taking a responsibility with which we have not been entrusted and neglecting to use fully the powers which have been given us. Surely with a surplus income of £1500 we can afford to do our duty in this respect, and show that we can safely be trusted to sternly enforce the poison regulations of the future.

GANDULPH.

Photographer.—(1) *Lysimachia nemorum*. (2) *Ajuga reptans*. (3) *Linaria cymbalaria*.

A. P. S.—It is open to doubt which preparation is intended; but in the event of not being able to refer to the prescriber, Lin. Bellad. Co. (Squire) would be the safer to dispense.

Tik.—Liq. Cinchonæ, B.P.

T. C. H.—The coloration has been frequently observed, but has not, so far as we are aware, yet been explained. Neither has it been noticed to be particularly associated with alkalinity. The subject appears to be worthy of further investigation.

C. J. B.—The mixture becomes opaque and there is a flocculent separation; but if the quinine, previously to its addition to the infusion, be dissolved in a little nitric acid there will be a little opacity, but no separation.

J. D. Pridgeon.—Tomes' 'Dental Surgery' (Churchill) and Coleman's 'Dental Mechanics.'

G. Horne.—(1) *Polygala vulgaris*. (2) *Valeriana dioica*.

G. S.—*Hypericum Androsæmum*.

S. H.—(1) *Prunus Lauro-Cerasus*. (2) *Fagus sylvatica* (purple variety). (3) *Aucuba Japonica*. (4) *Betula alba*. (5) *Alliaria officinalis*. (6) *Euonymus japonicus*. We cannot undertake to name garden plants. The specimens sent should include stem, leaves, and, when different in character, the root leaves also.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Horne, Morton, Bolton, Saul and Co., Wood, Lyle, Alpha, Neophyte.

NOTES ON RECENT DONATIONS TO THE MUSEUM OF THE PHARMACEUTICAL SOCIETY.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

II.—ESSENCE OF LIMES FROM TRINIDAD.

In March last there was offered for sale in the London market some oil of limes which differed very considerably in flavour from previous consignments. A sample of this oil, presented to the Museum by Messrs. Wright, Layman and Umney, was so exceedingly fragrant and bore so strong a resemblance in colour and odour and taste to the finest or "perfumer's" essence of lemon that it was difficult to believe that it could have been obtained from limes. Under these circumstances, I asked Mr. J. O. Braithwaite to compare it with other commercial samples of the oils of lemons and limes, and he reported as follows:—

At 60° F.	Essential oil of limes, Trinidad.	Essential oil of limes, commercial	Essential oil of lemon, *a*.	Essential oil of lemon. *β*.

"The solubility of the Trinidad oil is very different from that of commercial essence of lemon. It is soluble in the proportion of 1 part in 5 of alcohol of sp. gr. 0·838; so is commercial oil of limes.

"Commercial oil of lemon is barely soluble in the same menstruum in the proportion of 1 in 15.

"The taste of the Trinidad oil, while quite different from that of commercial oil of limes, has a slightly peculiar, but not unpleasant after-taste."

Being puzzled to know why an essential oil differing so much in flavour from ordinary oil of limes should be exported under that name, I made inquiries of Mr. H. Prestoe, the Director of the Botanical Gardens at Trinidad, who has sent the following interesting information:—

"Your remark that the odour of the oil is rather that of lemons than of limes is quite correct. It is to be observed that the odour of West Indian limes, as produced here, is rather that of lemons, as produced in Europe, than of limes produced there. The young shoots and all tender parts of the lime here have the odour of *Aloysia citriodora*,* the stronger lime odour being developed in the older parts. In the treatment of the fruit for obtaining the essence, the more rapid the process, the more pronounced is the lemon odour in the result if perfectly fresh fruits are used. The strong flavour of limes, more or less tinged with that of turpentine, seems to be a result of treating stale or decomposed fruit tissue. The plan adopted, on economic grounds, in Dominica and Montserrat, of crushing the limes as received from day to day and then, on the attainment of a large quantity of pulp, proceeding to boil down or distil, seems completely preventive of a fine flavour in the resulting essence when obtained. I might mention also that in some of our samples the essence has been obtained from lemons mixed with the limes, the two being grown on the same field and worked off by hand together. I may add that our limes are the finest in the West Indies, and are produced on trees quite unmatched for size and exuberance in any part known to me in the Western tropics."

The mystery is thus solved. If this product can be placed on the market at a price to compete with the Sicilian article and of quality such as the sample now in the Museum of this Society, there is every probability that it will soon come into demand for purposes of perfumery and culinary flavouring, etc., for which it is peculiarly fitted by its pure fragrance and great solubility in alcohol.

* I had inquired in my letter whether the oil was obtained from lemons or from the lemon-scented verbena (*Aloysia citriodora*).—E. M. H.

THE CHEMICAL PHARMACY OF THE NEW PHARMACOPÉE FRANÇAISE.

(*Continued from page* 987.)

Petroleum marks an entirely new departure in the chemical section of the Codex, and it is introduced under the general name of Pétrole d'Amérique. The different petroleums are a mixture of a great number of homologous hydrocarbons, varying in consistence, density, boiling point, and inflammability. Their products, which are themselves mixtures, are used in certain chemical and galenical preparations.

Essence de Pétrole blanche (light petroleum oil), is a colourless or slightly yellow liquid, non-fluorescent, of a peculiar penetrating odour resembling that of benzine. Density from 0·700 to 0·710. Distilling between 70° C. and 110° C. (158° F. and 230° F.)

This oil is insoluble in water, but completely miscible in absolute alcohol. Vapour ignites spontaneously at an ordinary temperature, with white, powerfully illuminating, sooty flame.

Huile de Pétrole Lampante (Huile minérale, H. pétro-solaire, Pétrole raffiné, Pétrole).—Colourless, often of an amber tint, blue by reflected light, of a less penetrating odour, and not unpleasant. Density not under 0·800, nor above 0·820. Distils at 150° C. (302° F.). This oil is insoluble in water and not miscible in absolute alcohol. Vapour not inflammable below 35° C. (95° F.). Extinguishes a lighted taper. Not coloured by an equal volume of pure concentrated sulphuric acid.

It is adulterated by other light and heavy petroleum oils.

Paraffine.—White crystalline substance, semi-transparent; slightly unctuous; extracted on cooling from heavy petroleum oils. Entirely devoid of smell and taste. Melts between 44° C. and 65° C. Distils between 280° C. and 400° C. Insoluble in water; sparingly soluble in boiling alcohol; freely soluble in ether, chloroform, bisulphuret of carbon, and the fixed and volatile oils. Density 0·875. A completely neutral body, resisting the action of acids and alkalies; heated with bromine a considerable quantity of hydrobromic acid is disengaged.

Pétroléine (Cosmoline, Graisse minérale; Pétroéline; Piméléine).—Petrolatum, better known under the accepted commercial term of vaseline. A mixture of heavy oils and paraffins more or less pure. Semi-solid, yellowish, unctuous. More or less fluorescent, specially when melted; without taste or smell; but with slight odour of petroleum when heated. Density between 0·835 and 0·860. Melts at 40° C. (104° F.). Distils at about 200° C. (392° F.). Insoluble in water and glycerine; sparingly soluble in boiling alcohol; readily so in ether, chloroform, bisulphuret of carbon, and in the fixed and volatile oils. A neutral body on which alkalies and acids have no action, cold; nor is it coloured by pure concentrated sulphuric acid. Entirely dissipated by heat. Vaseline is adulterated by fixed oils, fatty and resinous bodies.

Phénol (Acide Phénique).—Carbolic acid, itself official, is used in the preparation of a solution called

Phénol Sodé Dissous,

or solution of phenate of soda.

Carbolic acid	70.
Liquor sodæ (caustic)	100.
Aq. destillat.	q.s.

Dilute the caustic soda with about half its quantity of water, and the acid, and bring up the volume to 1 litre.

The solution is a novelty; the acid, not.

Phosphorus (white ordinary) and red phosphorus are both official. In preparing the phosphoric acid of pharmacy, the red substance is now employed, while the quantity of nitric acid has been increased. Phosphorus is directed to be kept under water, with the "essential precaution" that it should run no risk of being frozen.

White phosphorus, which is marked as *very poisonous*, is called normal; and red phosphorus, stated to be innocuous, constitutes Phosphore Amorphe. Phosphure de Zinc has been added, though the value of the preparation is not apparent; and a series of well-known alkaline phosphates presents no special interest.

The *Pyrophosphates* have survived the flight of time and certainly deserve a place in elegant pharmacy. They had a temporary reputation amongst ourselves, but have disappeared from medical practice. The Pyrophosphate de Fer Citro-Ammonical; and the Pyrophosphate de Soude (Sodæ Pyrophosphas) are unaltered; while the Pyrophosphate de Fer et de Soude (Pyrophosphas ferrico-sodicus) is new. The scale pyrophosphates make very attractive syrups.

Tannin (Acid Tannique, Acide Gallotannique) may claim to have had its pharmacy re-written. While Tannin Officinal is in the main unaltered, the process formerly given for its manufacture on a large scale has been omitted and two new preparations have been introduced.

Tannate de Quinine.

Quinine hydrate
Acid, acetic (1·060)
Acid, tannic. puv.

Quinia, mixed with water raised to the boiling point, is dissolved in sufficient acetic acid so as to make a feebly acid solution. On cooling, add by degrees to the liquor a filtered cold solution of tannin until the precipitate formed at the first is redissolved and neutralize exactly by sodium bicarbonate. The whole of the tannate of quinine is precipitated; it is collected on a filter, dried and finely powdered; then washed with distilled water, and dried a second time. The tannate is an amorphous, colourless salt, containing 20 to 21 per cent. of quinine.

Tannate de Pelletiérine.

Punica granatum (dried root bark)	1000 grams.
Quick lime	60 grams.
Chloroform (rectified commercial)	375 grams.
Sodium bicarbonate (powder)	q.s.
Dilute sulphuric acid	q.s.
Liquor sodæ (caustic) 1·332	10 grams.
Tannin, pure	q s.

Slake the lime and make it into a thick milk; roughly bruise the bark; damp the powder with the milk of lime and place in a convenient vessel. Percolate with distilled water so as to have 2 litres of liquid. Shake this up with 250 grams of chloroform; let the mixture stand, and separate, by means of a funnel with tap, the chloroform which has dissolved the alkaloids set free by the lime. Shake the chloroform solution with 60 grams of distilled water, adding gradually a 10 per cent. solution of sulphuric acid until a slight acid reaction is produced. The alkaloids are thus converted into sulphates. Add powdered sodium bicarbonate in slight excess; two alkaloids destitute of tænifuge properties are thus set free, and on being agitated will pass again into the chloroform. Separate the latter and replace it by 125 grams of fresh chloroform, then add to the mixture 10 grams of caustic soda lye and well shake. This will isolate from their salts two tænifuge alkaloids, Pelletiérine and Isopelletiérine, which will disolve in the chloroform. Separate the latter and shake with 60 grams of distilled water, and $\frac{1}{10}$ sulphuric acid added gradually until a *very feeble* acid reaction is produced.

The two tænifuge alkaloids will remain as sulphates in the water. Put the solution in a porcelain capsule under a bell glass and expose for some days over concentrated sulphuric acid. The sulphates of pelletiérine and isopelletiérine will form a crystallized residue in the capsule.

The mixture of these two salts is called, for short, sulphate of pelletiérine.

To convert the sulphate into tannate, weigh and dissolve in distilled water, and add a solution of tannin containing 3 grams, 28 c.g. of tannin for each gram of sulphate; neutralize exactly by ammonia. Throw on a filter and wash the precipitate until the washings no longer cause turbidity in a solution of barium nitrate. Dry with gentle heat. When wanted for use, powder the prescribed quantity of tannate; suspend in fifty times its weight of water, and dissolve by a gradual addition of solution of tartaric acid with continual shaking.

The Tartrates do not call for notice. Those of Ammonio-Tartrate and Potassio-Tartrate of Iron have been deemed sufficient to replace the old Teinture de Mars tartarisée, the composition of which was variable and uncertain.

The Valerianates of Ammonia, Atropine, Quinine and Zinc present no novelty.

The adoption of a alphabetical arrangement in the new Codex, with its manifest advantages, has upset the old classification under distinct headings in separate chapters, rendering some amount of reference necessary to gain the full information respecting any particular substance. We have, therefore, no longer Les Alcalis Végétaux included in Chapter XVI. of 1866, or the Sels à Bases Végétales of Chapter XVIII. The general index, consequently, rises into importance, and must be diligently consulted. In this section the Chlorhydrates have been extended, and even Chlorhydrate d'Ammoniaque, the Sal Ammoniac which is common to pharmacy, has been taken out of a mere official list and appears as a newly described chemical preparation.

Apomorphine, by reason of date, is a novelty. It is distinguished from morphine by its solubility in ether and chloroform. It gives a rose colour when treated with very dilute solution of perchloride of iron; readily oxidizable in the air; the product of this oxidation being soluble in water and alcohol. Apomorphine contains no water of crystallization, and should be completely soluble in chloroform without coloration. No process is given either for apomorphine or its chlorhydrate.

Morphine, on the other hand, has full details of manufacturing process added, with short processes for the Chlorhydrate de Morphine and the Sulfate de Morphine Neutre.

Aconitine in a crystalline form but retaining no water of crystallization is prepared by an altered formula. The preference given to the amorphous substance which was formerly stated to be much more active than crystalline aconitine appears to have been abandoned.

Azotate d'Aconitine (Nitrate of Aconitine) is made thus:—Powder crystallized aconitine; mix with about five times its weight of water, and exactly saturate with nitric acid previously diluted with five times its weight of water. Evaporate over the water-bath, and crystallize on cooling.

Two other nitrates are new introductions.

Azotate de Strychnine (Strychniæ nitras), the process for which is given as well as for Strychnine itself, and the extraction of the latter from Nux Vomica. It may be added that the method for the separation of Brucine is also detailed, and if we are to interpret literally the passage which declares that where a process of preparation has been appended, such products can or ought to be obtained by pharmaciens, we must allow that the requirements of French pharmaceutical chemistry are higher than our own.

Produits obtenus mean here clearly products obtained by home manufacture, distinguished from commercial products obtained from ordinary trade sources.

Azotate de Pilocarpine.—An entirely new nitrate, the process for its extraction from the leaves or bark of Jaborandi being given. The salt is purified by repeated crystallization in boiling alcohol. From this nitrate pilocarpine is prepared by the addition of ammonia up to alkaline reaction, and chloroform, which last dissolves the liberated alkaloid. The filtered chloroform solution is evaporated to a colourless syrup, which, to use the curious phrase of the Codex, "n'est autre chose que la pilocarpine." Chlorhydrate de Pilocarpine is the above dissolved in hydrochloric acid diluted with three times its volume of water; evaporate and crystallize.

It would be unfair to criticize French official chemistry by English notions; evidently special importance is attached both to Amorphous Digitalin, and to the Crystalline variety. Full details of process are given with respect to both; Digitalin in crystals has more than three pages devoted to its mode of preparation.

Digitaline Amorphe should always be used in a prescription where no particular kind is indicated. It is a white powder with a tinge of yellow, and possessed of an aromatic odour *sui generis.* Its essential character is stated to be the emerald green colour communicated on addition of hydrochloric acid. It is finally produced by spontaneous evaporation from chloroform, in accordance with the view entertained in 1866, that digitaline so purified was twice as active as that which had not undergone this treatment.

Digitaline Cristallisée is made from digitalis leaves "des Vosges," collected the second year at the flowering period. Chloroform is its best solvent; heated in contact with hydrochloric or phosphoric acid, it dissolves and the liquid assumes a fine emerald green coloration.

Atropine and its salts do not call for notice; and the same remark applies to Codéine, Santonine and Vératrine.

Caféine, Hyoscyamine, Narcéine and Vanilline are official and new introductions. Certain substances and preparations admit of no classification, and a reasonable surprise may be occasionally felt at their insertion. Acide Picrique (Carbazotic acid) is official; and so is Bitume de Judée (Asphalt.)

Cantharidine, with new process of extraction, is retained.

Picrotoxine has been promoted to a place of honour, as also Iodoforme. Dextrine, which we are used to class amongst commercial articles, is recognized in French chemical pharmacy.

The object of these sketches has been to give in convenient space some information concerning the preparations contained in the "Chemical Pharmacy of the New Pharmacopée Française," which are either novel or distinctive; where no real points of difference existed between French and English formulæ, reference has been omitted.

To assist the memory of the reader a few popular names are subjoined, which are sanctioned by common use.

ACIDE AZOTIQUE = Nitric acid.
ACIDE PHÉNIQUE = Carbolic acid.
ALCALI VOLATIL = Liquor ammoniæ.
ALCALI VOLATIL CONCRET = Ammoniæ sesquicarbonas.
BITUME DE JUDÉE = Asphalt.
BLANC { D'ESPAGNE / DE MEUDON / DE PARIS } = Carbonate of lime.
CALOMEL À LA VAPEUR = Mercurous chloride.
CAMÉLÉON VIOLET = Potassium permanganate.
CAMION = Vessel in unglazed earthenware, such as those in which benzoic acid or calcined magnesia is prepared.
CAMPHRE DU JAPON = Camphora officinarum.
CÉRUSE = Lead carbonate.
COLLE DE FLANDRE = Gelatine, or purified, Grénétine.
COSMOLINE = Vaseline.
COUPEROSE { BLANCHE = Zinci sulphas. / BLEUE = Cupri sulphas. / VERTE = Ferrous sulphate.
CRAIE DE BRIANÇON = Talc.
CRISTAL MINÉRAL = Fused nitre.
EXTRAIT DE SATURNE = Liq. plumbi diacetatis.
GOUDRON DE HOUILLE = Coal tar.
KARABÉ = Succin (ambre jaune).
LESSIVE DES SAVONNIERS = Caustic soda lye.
LIQUEUR DES CAILLOUX = Solution of potassium silicate.
LIQUEUR DE LABARRAQUE = Solution of hypochloride of soda.
MAGISTÈRE DE BISMUTH = Bismuthi subnitras.

MAGISTÈRE DE SOUFRE = Precipitated sulphur.
MERCURE DOUX = Calomel.
NOIR D'OS = Animal charcoal.
OFFICINAL. In Codex (Chemical section) = Prepared for pharmaceutical use.
PHOSPHORE AMORPHE = Red phosphorus.
POINTES DE PARIS = Ferri limatura.
SAFRAN DE MARS APERITIF. = Ferri subcarbonas.
SEL DE BERTHOLLET = Potassium chlorate.
SEL DE DUOBUS = Potassium sulphate. (K_2SO_4.)
SEL D'EPSOM DE LORRAINE = Common sulphate of soda. Purified = Glauber salt.
SEL GEMME = Commercial sodium chloride. Sea salt.
SEL DE NITRE = Potassium nitrate.
SEL D'OSEILLE = Binoxalate of potash.
SEL DE PHOSPHORE = Phosphate of soda and ammonia. (Phosphas ammonico-sodicus.)
SEL DE SATURNE = Diacetate of lead.
SEL DE SEDLITZ = Magnesium sulphate.
SEL DE SEIGNETTE = Sodæ potassio-tartras.
SEL DE SOUDE = Soda exsiccata (commercial).
SEL DE SOUDE CRISTALLISÉ = Carbonate of soda, crystals. ($Na_2CO_3 + 10H_2O$.)
SEL DE TARTRE = Carbonate of potash (pure). (K_2CO_3.)
SEL DE VICHY = Bicarbonate of soda.
SUCRE DE SATURNE = Diacetate of lead.

THE BITTER SUBSTANCE OF HOPS.*

BY DR. H. BUNGENER.

Little that is definite is known of the substance or substances to which the hop owes its bitterness. Lermer has succeeded, it is true, in separating from hops a crystallized colourless substance, insoluble in water, an alkaline solution of which has a marked bitter flavour, and which easily changes on exposure to the air, assuming a resinous form. According to Lermer, the formula of this substance is $C_{32}H_{50}O_7$; it possesses the properties of a weak acid and forms a characteristic copper salt, which is soluble in ether. This hop bitter is, however, produced from the hop by a very roundabout process, by treatment of the extract with alkalies; it is not therefore regarded by many as present in this form in the hop. and they hold that it is only produced by the action of the alkalies. On the other hand, however, Etti, by a complicated extracting process, but without using an alkali, succeeded in producing a bitter substance from hops, which is, however, soluble in water.

Several experiments convinced me that there really existed in hops a crystallizable substance, insoluble in water, the alcoholic and alkaline solution of which had a bitter flavour, in short, which possessed all the properties of Lermer's hop-bitter acid. Petroleum ether is the best practical solvent in use for its isolation, as it does not dissolve the majority of the remaining constituents of the hop, especially the hop-resin, which they contain in considerable quantity. Still, the extraction of hop-bitter acid from hops is a troublesome and thankless job, the petroleum ether taking up certain substances which add greatly to the difficulty of purifying the crystals. On the other hand, we can readily and quickly attain our object, if we employ for our original material fresh lupuline from unsulphured hops.

The following process has furnished me the best results:—

The lupuline is first freed from gross impurities (hop-seed, leaves, etc.), and then covered with petroleum ether boiling at a low temperature (40° to 70°) in stoppered flasks. The mixture is shaken up from time to time. After twenty-four hours, by means of a Zullowsky filter immersed in the mass, and with the aid of a suction-pump, the dark brown solution is drawn off; then fresh ether is poured on to the lupuline and it is allowed to stand for another twenty-four hours. After this process has been three times repeated, nearly everything the petroleum will dissolve has probably been extracted. The solutions are put together and the petroleum ether distilled off *in vacuo* at a low temperature, until there remains in the flask a dark brown syrup, which on cooling solidifies into a crystalline mass. This is pulverized and turned on to a filter composed of a large funnel, in which a smaller funnel covered with muslin is inserted. With the aid of a suction-pump, the greater portion of the thick, crude solution can be filtered through. There remains on the filter a highly coloured crystalline "cake," which should be pulverized with a small quantity of petroleum ether and again filtered. After this operation has been repeated three or four times, we obtain an almost colourless mass, consisting of hop-bitter acid, contaminated by small quantities of a fatty substance and a substance which I could not isolate, and which I had at first great trouble in separating from the hop-bitter acid.

If we do not wish to utilize this crude substance at once, it will be necessary to melt it in the water-bath and pour it into a bottle under close seal, where it will at once crystallize and solidify. If it remains exposed to the atmosphere it will soon become sticky and turn partly into resin. Six kilos of lupuline, which included a large proportion of sand, furnished 400 grams of crude hop-bitter acid. The first experiments in crystallization with petroleum ether gave poor results; it is difficult to produce the acid pure in large quantities by this process, as a small quantity of the above substance obstinately clings to it, and it readily assumes a non-crystallizable form. Our object is more readily attained if we crystallize it once from alcohol, for which purpose we dissolve it in a little lukewarm alcohol, then quickly cool the solution; flakes of a fatty substance will be separated, which are removed by filtration with the aid of a suction-pump. Then we throw a few small crystals of the acid into the solution, and after a short time crystallization commences. As soon as it appears to be ended, the mother solution is removed with the aid of a platinum cone, and the crystals washed with a little cold alcohol. The alcoholic mother solution, which still contains the chief part of the bitter acid, must be quickly evaporated, and the residue consigned to a flask. The acid crystallized from the alcohol is then re-crystallized several times from petroleum-ether. In order to quickly dissolve the bitter substance, it should be carefully melted in a flask and double its volume of ether gradually added; on its cooling, we obtain beautiful prismatic crystals, which attain a length of 1 cm., and become perfectly pure after four or five crystallizations. The mother solutions must be speedily evaporated if we still wish to obtain crystals; after a time they will only furnish a resinous residue.

The hop-bitter acid melts at 92° to 93°. It is easily soluble in alcohol, ether, benzol, chloroform, sulphide of carbon, and vinegar; to a lesser extent in cold petroleum-ether, and not at all in water.

In the analysis I obtained figures which correspond best with those calculated from the formula $C_{25}H_{35}O_4$.

	Calculated.	Obtained.					
		2. Crystal.		3. Crystal.	5. Crystal.		6. Crystal.
	p. c.	p. c.	p. c.	p. c.	p. c.	p. c.	p. c.
C	75·19	74·79	74·83	74·9	75·04	75·05	75·07
H	8·77	8·97	8·90	8·85	8·87	8·83	8·80
O	16·04						

If we shake up the ether solution of bitter substance with an aqueous solution of acetate of copper, the ether will assume a green colour and gradually deposits a green crystalline powder, a cupreous combination of the bitter acid. It is difficult to obtain in a pure state, as the solutions are readily subject to slight decomposition, accompanied by a small deposit of copper oxide. This combination is readily soluble in alcohol, to a lesser extent in ether, and is insoluble in water.

* *The Brewers' Guardian, from the Zeit. f. d. gesammte Brauwesen.*

In the course of analysis, I obtained the following figures:—

C	69·4 per cent.	69·3 per cent.
H	7·95 „	7·98 „
Cu	7·20 „	7·18 „

If we suppose that the copper combines with two molecules of hop-bitter acid, by the decomposition of one of its atoms, H, we obtain the formula $C_{50}H_{68}O_8$ Cu. This combination will contain 69·87 per cent. C, 7·91 per cent. H, and 7·33 per cent. Cu. The figures obtained do not perfectly coincide with those calculated; it is nevertheless probable that the formula is correct, and the combined substance analysed was not perfectly true.

I have already referred to the fact that solutions of hop-bitter acid, if left standing too long, assume a yellow colour, and on evaporation leave only a yellow resinous residue. This, as its reaction shows, evinces a complete analogy with the crystallized acid. The dark-coloured mother solution, from which the crystalline cakes of bitter acid are obtained, contains a large proportion of this resinous compound, which can be isolated by treatment with a weak soda-lye; this substance, like the crystallized acid, is soluble in alkalies, and can be precipitated from an alkaline solution by an acid. Old hops furnish far less crystallizable acid than new hops; from some samples I have been able to obtain only a few crystals; the remainder had been transformed into the resinous modification.

If pure hop-bitter acid be pulverized and exposed to the atmosphere it soon turns yellow and the surface assumes a resinous consistency. At the same time, a more pronounced odour of fatty acids and aldehydes is apparent. Still more rapidly will this oxidation occur if a thin layer of an alcoholic solution of the acid is allowed to evaporate in the air. On the other hand, we can allow hop-oil to stand for days without its odour being perceptibly changed; it appears to me more than probable that the peculiar smell of old hops is due far more to the oxidization of the bitter substance than to the oxidation of oil.

Hop-bitter acid appears to possess the character of an aldehyde and of a weak acid; for the present I am not in a position to state its constitution more clearly. Most of the oxidizing processes have an energetic effect on it, forming also considerable quantities of valerianic acid.

The question as to whether the hop owes chiefly to this acid and its resinous modifications the property of imparting a pronounced bitter flavour to a solution, I must for the present leave unanswered. The acid and its isomer are both insoluble in water; they are, on the other hand, very readily dissolved in hop oil; they also furnish a tolerably bitter solution, if boiled for a long time in water, probably on account of their gradual decomposition. I will not for the present go further into the subject, as I hope soon to be in a position to give more definite information.

THE ECONOMIC APPLICATIONS OF SEAWEED.*

BY EDWARD C. C. STANFORD, F.C.S.

In 1862, twenty-two years ago, I had the honour of reading a paper before the Society of Arts, on this subject, in this room. The council marked their appreciation of that paper by awarding me a silver medal, and I cannot forget that the honours of that year were shared by another chemist, my friend, Dr. Crace Calvert, once so well known here, but who has since passed away. When, therefore, I was again invited a little while ago to read a second paper, I felt that some apology was due for not returning to report progress before. I am bound to admit that, like some wanderers through space, the period has been long and the orbit eccentric. For the former I must plead the difficulty of the subject; for the latter I must remind you that any one who follows seaweed must go to the wildest and most inaccessible shores.

It is extremely interesting to me, and I trust it may be made somewhat entertaining to you to look back on that paper, with the light of over twenty years' experience, and see how far the views then put forward were right, and how far they were wrong, premising that even failures are excellent lessons. "Many things have happened since then," and new and better sources have been discovered of many of the products then brought forward for the first time. As, however, it may be advisable to follow the lines of that paper, I shall first briefly allude to the uses of seaweed for food and for manure, and then speak more at length on the important application of these in the manufacture of kelp, and the production of iodine.

Seaweed as Food.—In this country little advance has been made in the use of the algæ as food. The algæ generally contain important nitrogenous constituents, and form nutritious articles of diet, but they have not been popular. We all like a "sniff of the briny," but we do not cultivate a taste for the internal consumption of our marine vegetables. We are equally guilty, however, in rejecting the majority of the fungi, so largely consumed as an important article of food on the Continent. The algæ are closely allied to these, but have the advantage of containing, as far as is known, no poisonous species. The algæ also contain a large proportion of salts which, however, are easily removed, if desirable.

Ulva latissima, or green laver, and *Porphyra laciniata*, or pink laver, are occasionally used in soups. *Rhodomenia palmata*, or dulse, is still sold in the streets of Edinburgh and Glasgow. *Alaria esculenta*, or murlins, is also eaten in Ireland. Some others are occasionally used, but, as a general food, the algæ are almost unknown. The sweetest species is the *Laminaria saccharina*, which is usually covered, when dry, with an efflorescence of mannite; a large quantity of this plant yielded me 7·47 per cent. of mannite. It appears to be a product of fermentation, and does not exist in the fresh plant. This plant is found only on sandy or gravelly shores.

The best known British species of the edible algæ is the *Chondrus crispus*, or Irish moss. This grows far down on the rocks, and is only uncovered at low spring tides. It is obtained mostly from the west coast of Ireland, and after being bleached by exposure to sun and rain, is largely exported to this country and to Germany. It is a gelatinous species, containing a principle known as carragheenin; it yielded me 63·7 per cent. of this substance.

The only other gelatinous British species is the *Gelideum corneum*. This is not very common, but it furnishes the import known as Japanese isinglass, of which it contains 50 per cent. This substance, known also as gelose, was first imported into France from China, in 1856; it has great gelatinizing power, much higher than any other material. It is not nitrogenous, and contains carbon 42·8, hydrogen 5·8, oxygen 51·4.

The following table shows the value of these species in making jelly. The melting point of the jelly is also appended.

1000 parts of water require of—

	Parts.	Proportion.	Melting point.
Gelose	4	1	90° Fahr.
Gelideum corneum	8	2	90° „
Irish moss (*Chondrus crispus*)	30	75	80° „
Isinglass	32	8	70° „
Gelatine	32	8	60° „
Carragheenin	36	9	70° „
Agar-agar (*Euchemia spinosa*)	60	15	90° „

It will be seen that gelose has eight times the gela-

---

* Read before the Applied Chemistry and Physics Section of the Society of Arts. Reprinted from the Journal.

tinizing power of isinglass and gelatine; but the melting point of the jelly is too high to allow it to melt quickly in the mouth, hence gelatine is still the favourite.

The carragheenin has evidently become altered by evaporation. Gelose jelly keeps well, the others soon get mouldy. Although not fit for jelly, gelose may be valuable in the arts as a substitute for gelatine, which it so much exceeds in gelatinizing power. I would specially suggest its use as a substitute for gelatine in the production of instantaneous photographs.

The *Euchemia spinosa*, or agar-agar, is an Australian alga, and another important gelatinous species. The algæ form a large article of food consumption in China and Japan. Some years ago I procured some of these samples, one was a dark green frond, and the other two were cut up from it, about the size of vermicelli. I append the analyses of these and of a sample of our own laminaria from Loch Eport in North Uist.

Edible Seaweeds.—Japan.

No. I.—"This is a good average sample, worth to-day, in this market, 11 taels, which, at 6*s.* 6*d.*, the average value of the tael, is 71*s.* 6*d.* per picul of 133 lbs.; therefore, one ton (16·75 piculs) would cost, in Shanghai, £57 4*s.* It can be cut finer, and then the price, if it is of the deep green which this is when it leaves me, would be about 14 taels per picul, or £72 10*s.* per ton."—*Extract from letters.*

The sample is green, and evenly cut about as fine as vermicelli.

No. II.—"This is the worst sample I can find, worth 2 taels, which is £11 8*s.* per ton. The uncut leaf would be more valuable than this if of the colour of No. I. It would fetch £16 per ton."—*Extract from same letters.*

This sample looks like the former deteriorated.

No. III.—This was apparently the uncut weed. It much resembles in colour and appearance No. IV.

No. IV.—Laminaria, cut in Loch Eport, North Uist; colour, dark green. Quotations by Mr. Frazer, Yokohama, September 18, 1868:—Fine cut, £17 9*s.* 8*d.*; fine brown, £15 10*s.* 9*d.*; large green, £9 14*s.* 2*d.*—per ton. Specimens of No. IV. were sent out to Yokohama, but they did not take the market. It is remarkable that so high a price as 72*s.* 6*d.* per cwt. (or nearly 8*d.* per lb.) should be realized there for this seaweed for dietetic purposes.

The taste for marine vegetables must be acquired, but those who have eaten them often are said to become very fond of them; and I have known some gentlemen in the Highlands, no mean judges of diet, who consider a dish of dulse, boiled in milk, the best of all vegetables. There is no doubt that a valuable food is lost in entirely neglecting the algæ; but I shall show, presently, how much of this may be recovered in an available form.

Seaweed as Manure.

This appears to me to be one of the worst applications of seaweed, and I do not think it has increased; farmers are beginning to find out that it seldom contains less than 80 per cent. of water, often more; and that for the actual manurial value in it, it may be very expensive if a long cartage is required. Four tons of water, at least, must be carted for every ton of dry manure, and when dried there is much additional expense, and it is very bulky. The dry weed contains an average of 2 per cent. of nitrogen, so that, as it is used, it contains less than ½ per cent. The chemical value is very little, except from the potash contained; but the mechanical value may be greater, as in covering root crops as a protection from frost, or where the soil is simply sand, and it binds it together. However, the cartage of water and the manufacture of soil are expensive amusements, and seaweed is not much used where there is high farming. It appears also, where continually used alone, to impoverish the soil; it is like feeding a dog on butter. The residue of seaweed ash, or kelp waste, one ton of which is equal to forty tons of wet seaweed, and contains all the phosphates, is quite unsaleable for manure in this country. It may be remarked, too, that in the wet climates of the west of Ireland, and of Scotland, where it is mostly used, the application of water is quite a superfluous operation for the farmer.

Another application of seaweed, which I mentioned before, was the manufacture of paper. As far as I know, this has only been carried out in France, on one plant, the *Zostera marina*, or grass wrack, a material largely used in this country for stuffing mattresses, and for packing light furniture. Some curious specimens of this plant, rolled up in little balls of fibre, were shown here at that meeting, as thrown up by the sea at Majorca and Minorca; and soon after it created a good deal of attention, having been proposed as a substitute for cotton; it contains little fibre, however. It grows in enormous fields, on sand-banks, and is widely distributed, and is to be found in almost every ocean; it is a pure marine plant, with flowers, having nothing in common with the algæ except the habitat. It is often found on the shore perfectly bleached. All the algæ are cellular, and contain no fibre, but properly treated they make a tough transparent paper, to which I shall have to allude presently.

The Manufacture of Kelp.

This crude substance which, for many years, made the Highland estates so very valuable, was at first made as the principal source of carbonate of soda. At the beginning of this century it realized £20 to £22 per ton, and the Hebrides alone produced 20,000 tons per annum. The importation of barilla then began, and for the twenty-two years ending 1822, the average price was £10 10*s.* The duty was then taken off barilla, and the price of kelp fell to £8 10*s.*; and in 1823, on the removal of the salt duty, it fell to £3; and in 1831, to £2. It was used up to 1845 in the soap and glass factories of Glasgow, for the soda. Large chemical works were then existing in the island of Barra, built by General McNeill, for the manufacture of soap from kelp, and a very large sum of money was lost there. Two tall octagonal chimneys were still standing not long ago, but have now succumbed to the gales. In the meantime, soda was being largely made by the Le Blanc process, and superseded kelp, which was always a most expensive source, yielding only about 4 per cent., often less than 1 per cent.; it must have cost the soap-makers what would be equal to £100 per ton for soda ash, the present price of which is £6.

The manufacture of iodine and potash salts then began to assume some importance, but the kelp required was not the same; that which contained the most soda containing the least iodine and potash. Chloride of potassium, the principal salt, was at one time worth £25 per ton. The discovery of the Stassfurt mineral speedily reduced this price to about a third, and the further discovery of bromine in this mineral also reduced the price of that element from 38*s*. per lb. to 1*s*. 3*d*., its present price. The amount of bromine in kelp is small, about a tenth of the iodine, and not now worth extracting. Large quantities are now produced in Germany and America. More recently, the manufacture of iodine from the caliche in Peru has attained large proportions, and has so far reduced the price of that article, as to make its manufacture from kelp unremunerative. In a paper, compiled for the British Association, published in 1877, I estimated the then total production of iodine in Great Britain and France at 2000 kegs of 1 cwt. each; and the future production of Peru at 6000 kegs; an estimate which is now being rapidly realized.

In 1882, the amount of iodine exported from Peru was 205,800 kilos, or 4116 kegs, divided as follows:—

To London	120,900 kilos
„ Hamburg	62,100 „
„ New York	22,800 „
	205,800 „

The present annual output is estimated at 300,000 kilos, or 6000 kegs.

On the other hand, the present manufacture of Great Britain and France is less than 1000 kegs, the production of France being now reduced to almost nothing, and the kelp sold as manure.

I append an abstract of a table in that paper, showing the imports of kelp into Glasgow, to which city or its districts the manufacture of British iodine has always been confined.

The prices given are the average prices for the year; higher than the maximum, but not lower than the minimum, have been reached. It is remarkable that we are now coming back to exactly the price of 1841, forty-three years ago, and also exactly to the price of twenty-two years ago, when my first paper was written. Potash salts, however, were then three times the present price.

Imports of Kelp into Clyde.

Five years, 1841 to 1845.

Tons of kelp, 1887 in 1844 to 6086 in 1845; average 3133. Price of iodine per lb., 4*s*. 8*d*. in 1842 to 31*s*. 1*d*. in 1845; average 11*s*. 9*d*.

Ten years, 1846 to 1855.

Tons of kelp, 3627 in 1846 to 11,421 in 1850; average 3627. Price of iodine per lb., 8*s*. 8*d*. in 1851 to 21*s*. 3*d*. in 1846; average 12*s*. 11*d*.

Ten years, 1856 to 1865.

Tons of kelp, 6349 in 1856 to 14,028 in 1863; average 9730. Price of iodine per lb., 5*s*. in 1863 to 13*s*. 8*d*. in 1856; average 8*s*. 10*d*.

Ten years, 1866 to 1875.

Tons of kelp, 8116 in 1868 to 10,923 in 1874; average 9187. Price of iodine per lb., 10*s*. in 1866 to 34*s*, in 1872; average 15*s*. 11*d*.

Seven years, 1876 to 1883.

Tons of kelp, about 6000 to 8000; average about 7000. Price of iodine, 5*s*. in 1883 to 15*s*. 6*d*. in 1879; average about 10*s*. 2*d*.

Total average kelp import, 1841 to 1883 (42 years) 6750 tons. Average price of iodine per lb., 12*s*.

So that the present price is only about 40 per cent. of the average value. The great fluctuation in the price, and the small bulk of the article in proportion to its value, and the limited production, have led to great speculation, and I have no doubt a few kegs might still be found here and there in London which were bought some years ago at a pretty high price, and are still waiting the improbability of a turn in the market.

The amount of iodine in sea water is so minute, that it is extremely difficult to detect by ordinary tests. By evaporating down two portions of sea water filtered and unfiltered, each over 14 gallons, and by employing a delicate colour test, I have succeeded in estimating it. The sea water was collected carefully in the Atlantic, west of the island of Tyree. I found in 1,000,000 grs. measure (14·2857 gallons) of unfiltered sea water, ·003572 or 1 in 280,000,000; in 1,000,000 grs. measure of filtered sea water ·003442 or 1 in 291,000,000. The unfiltered water might be expected to contain more iodine from minute algæ in suspension, although it appeared clear. Kortstoffer, who estimated it in the Mediterranean, puts it at 1 part in 50,000,000. Bromine is easily detected; sea water generally contains about 6 parts in 100,000, and of chlorine about 2 per cent. Professor Dittmar, who has been working out the sea water samples of the *Challenger* expedition, has discovered a remarkable relation between this element and that of the chlorine which he has kindly communicated to me. He finds the relation in the great number of samples examined (77) to be constant in the proportion of ·340 bromine to 100 chlorine. He finds the average amount of chlorine to be 1·9 per cent., or 19,000 parts in 1,000,000, and of bromine ·00646 per cent., or 64·6 parts in 1,000,000, or 18,422 times as much as my mean result for the iodine. The Woodal Spa has been long known to be very rich in iodine and bromine; a recent analysis by Wright giving of chlorine 11113·73 parts per million, bromine 49·7 parts per million, iodine 5·21 parts per million. Here the relation of bromine to chlorine is ·44 to 100, and the iodine about a tenth of the bromine; in sea water the proportion of iodine is a very minute fraction of this. Examination of the brine and the mother liquor from the salt mines of Cheshire failed to detect iodine. The algæ possess the power of assimilating the iodine to about ten times the extent of the bromine. I append estimates of iodine in a number of algæ, those of the Laminaria and Fuci are the average of a great number of specimens collected at different times of the year, and all round Great Britain and Ireland, the Channel Islands, and the Isle of Man, and including Orkney and Shetland, Iceland, Denmark, and Norway. I append also estimates of the iodine in several of the giant algæ in the Falkland Islands, for which I am indebted to Governor Kerr, and Mr. F. G. Cobb, of the Falkland Islands Company.

These gigantic species are seen in this country for the first time in the fresh state, and little is known about them. The macrocystis is said to grow to a length of 1500 feet, or over a quarter of a mile in length. It grows in 10 fathoms water in Stanley Harbour.

The *d'Urvillea* forms stems branched like trees, 12 feet or 14 feet long, and a foot in diameter. All these weeds are thrown up in enormous quantities on the shores of the Falkland Islands, and along the Straits of Magellan, making it difficult for a boat to approach them.

Falkland Islands Giant Algæ.

		Per cent.	Lbs. per ton.
D'Urvillea utilis,	No. 1	0·0075	·179
,, ,,	No. 2	Trace	—
Lessonia	No. 1	0·0284	·636
,,	No. 2	0·0181	·405
Macrocystis pyrifera		0·0308	·690

In the foregoing table the Laminariæ and the Fuci are the kelp-producing species.

It is remarkable that the three gelatinous species, *Chondrus*, *Gelideum* and *Euchemia*, contain little or no iodine.

It is noticeable, too, that the *Enteromorpha*, or sea grass, a plant which retains, when dry, a very strong odour of the sea, contains no iodine.

It is also remarkable that the giant algæ contain so little iodine, growing outside the influence of the Gulf Stream, which, rightly or wrongly, has been supposed to be the iodine carrier. It is a curious fact that there are certain seeds, supposed by the natives to grow on the tangle, and called "tangle nuts." A specimen here from Tyree is evidently the seed of a leguminous American tree, brought over by the Gulf Stream.

It is probable that all animal substances from the sea contain iodine; its presence has been long known in cod-liver oil, a substance supposed to be rich in it, and to owe most of its valuable medicinal property to it, but I found, after investigating a good many various specimens of this oil, that the amount is infinitesimal. The liver itself contains double as much. Oysters, especially the Portuguese variety, have also been said to contain a good deal. The following are my results:—

		Per cent.
Cod liver oil, average of six specimens		·000322
Cod liver, fresh		·000817
Salt cod fish	48·5 per cent. water	·000255

(*To be continued.*)

VESICATING AND PURGATIVE PRINCIPLES OF CROTON OIL.*

BY R. H. SMILEY.

This is the subject of a paper by Mr. Harold Senier (*Pharmaceutical Journal and Transactions*, December, in which he gives results of his investigations.

To verify his results, I have made numerous experiments, both as to the separation and the action of the parts when separated.

Mr. Senier states that croton oil is soluble in alcohol, by taking equal volumes of each, or less proportion of alcohol; but when more alcohol was added a separation occurred, one part of which was entirely non-soluble, and was found to contain the purgative principle of the oil, whilst the part which was soluble contained the vesicating part. With a sample of croton oil I first made experiments as to its solubility, and found that by taking 10 minims of oil and 5 minims of alcohol a perfect solution occurred after slightly heating; but taking 10 minims of alcohol and 5 minims of oil a separation into two parts remained unchanged by the same amount and even more heat than made a solution of the other proportion. I next put a quantity into a test tube, and added more than equal volumes of alcohol, and after shaking and allowing to stand for a while the soluble part, which, being the lighter, at once rises to the top, was decanted into another vessel. This washing with alcohol was continued until all the soluble part was removed, which was shown by the alcohol, after shaking, rising to the top colourless.

The liquid part removed from the non-soluble was applied to the skin in several places, and in due time a pustular eruption showed, as might be expected, by the external application of croton oil. I then tried some of the insoluble part in the same way, and no sign of any eruption whatever appeared. I made pills of the non-soluble part, and let each one represent ¼ of a minim, and began by taking the half of one pill, which produced no effect other than slight nausea. The dose was increased gradually, and resulted about the same as experiments made by Dr. John W. Meek, of London, who used some of the non-soluble part of the oil prepared by Senier. I found that ½ minim of the isolated part acted as a pretty strong purgative, and the first action generally occurred in from twenty minutes to one hour from time of taking. The action of the vesicant and purgative parts was further verified by experiments on others, and the general result was about the same as given above. There was no griping in any case, and the most unpleasant symptom of the action was slight nausea, which was no more than one would expect from any purgative dose of medicine.

Croton oil will, in the future, be more useful as a remedy than it has been in the past, especially as to internal administration, which has heretofore been accompanied with very unpleasant effects on account of the vesicant principle, but this evil being now removed the good results of the purgative principle are ready for investigation.

BARBADOES ALOES IN ST. HELENA.

In a recent report on the Island of St. Helena, Mr. Morris, of the Royal Botanic Gardens, Jamaica, says:—

"Another member of the aloe family, which is very abundant in the island, and capable of being largely utilized, is the Barbadoes aloe (*Aloe vulgaris*). It grows freely in Jamestown Valley in volcanic ash, and on barren rocks. It is fast spreading also in Rupert's Valley; and I noticed it was there used, and seemed to flourish, as a coping for a stone wall.

"This plant, so hardy and prolific, produces the aloes of medicine, and it is cultivated, especially at Barbadoes in the West Indies, solely for this purpose. It reproduces itself by means of suckers around the stem; these being removed when about six inches high are planted out on waste pieces of land, about two feet apart. When fully grown, and just before flowering, the outer and older leaves are first removed; they contain an abundance of a thick yellowish juice, which is allowed to drain into troughs leading into a large iron pot or caldron. When the pot is nearly filled it is placed over a fire, and the juice boiled until it has attained the consistency of thick glue; this when cool is the aloes of commerce, and it is usually exported to England in bottles or gourds.

"Barbadoes aloes, prepared in the manner above indicated, is valued in the London market at £4 to £8 per cwt. It is usually retailed by druggists at 4*s*. 6*d*. per pound. This industry, which necessarily must be very small, might commend itself to the notice of many people, especially fishermen and others, living in the lower valleys. The plant is abundant; its cultivation, if merely putting a few suckers in the ground can be so called, is of the simplest description; and the preparation of the juice requires only a few troughs, made by nailing a couple of pieces of board at right angles to each other, and an iron pot. If some local tradesmen were to give attention to the subject, and undertake to purchase the manufactured aloes from the cultivators in small quantities, the industry would soon be placed upon a satisfactory footing."

The Pharmaceutical Journal.

SATURDAY, JUNE 14, 1884.

THE ROYAL COMMISSION ON TECHNICAL INSTRUCTION.

THE preliminary volumes of the Second Report of the Royal Commissioners who were appointed, about two years since, to inquire into the instruction of the industrial classes of certain foreign countries in technical subjects, and the influence of such instruction upon manufacturing and other industries, have just been issued. They contain a large amount of valuable information respecting technical education on the Continent and in the United States, as well as observations made during visits to various industrial establishments, together with the conclusions to which the Commissioners have come after careful consideration of what they have seen abroad and comparison with the conditions that prevail in Great Britain. The Report is one that is worth careful pondering in this country, for whilst there is enough in it to confirm our national egotism, there are also plenty of facts which should act as monitions that if Great Britain intends to continue at the head of industrial nations she must bestir herself and equip her sons in the best possible manner for the struggle. Indeed the Commissioners confess that although the display of continental manufactures at the Paris Exhibition had led them to expect great progress, they were not prepared to find so remarkable a development of natural resources and such perfection in industrial establishments as were actually met with in France, Germany, Belgium and Switzerland. Indeed, in some branches of industry, more especially in those requiring an intimate acquaintance with organic chemistry, Germany has already taken the lead. Two years ago, Professor ROSCOE publicly expressed his regret that the rough products of coal tar were exported from this country to Germany and re-imported in the form of products of greatly enhanced value. In Belgium, the introduction by SOLVAY of the ammonia process for the manufacture of soda has struck a heavy blow at our previous pre-eminence in the alkali manufacture. Moreover, in the economical production of coke, and the recovery of the tar and ammonia formed in this process, we are only now slowly following in the footsteps of our continental neighbours. On the other hand, the Commissioners point out that most of the principal new industrial departures of modern times have been due to the inventive power and practical skill of our countrymen. For instance, it is to the invention of BESSEMER, either alone or in conjunction with the modifications introduced by THOMAS and GILCHRIST, that the present enormous production of steel at one-tenth of its former cost is due; the processes of WELDON, HARGREAVES and DEACON have revolutionized the alkali trade; and the manufacture of aniline dyes owes much to the initiative of PERKIN.

Of course it would be impracticable in these columns even to glance at a tithe of the numerous topics referred to in the Report; we must content ourselves with indicating briefly the explanation that appears to be favoured by the Commissioners of the wonderful advance that has been made by our neighbours, especially in those industries that may be supposed to present special points of interest to the readers of this Journal. Contrary to what might be expected, the Commissioners do not find this explanation in the resources of continental countries for the technical education of workmen outside of the workshop, which are said to be very much more limited than has hitherto been supposed in this country to be the case. It is true that in many important centres there are societies, supported mainly by the manufacturers of the district, having for their object the promotion of education among workmen by means of lectures and the establishment of schools and museums of technology. But although these societies are numerous their sphere of action is limited, and the Commissioners consider that the facilities they offer for evening instruction in science and technology are inferior to those which are at the disposal of our own workmen. There are also technical schools for boys aspiring to become foremen; but it was found that, although, a few of the foreign foreman met with had received theoretical technical instruction, this was not generally the case, and the majority of them were, as in this country, men who by superior steadiness, intelligence and capability for management had raised themselves from the position of ordinary workmen. Nevertheless the Commissioners do not ignore the value of such instruction to the rank and file of mechanics, as is shown by their recommendations framed to secure a more sound and thorough teaching of science, drawing, and the use of tools, even in our primary schools. They forcibly argue that as it is from the great mass of the working population, who have to begin earning a livelihood at an early age, that most foremen will probably continue to be selected, it is even more essential for them than for the community in general that instruction in the rudiments of the sciences bearing upon the industrial arts should form a part of the curriculum of elementary schools. But it is to the technical high schools —such as the Ecole Centrale of Paris and the Polytechnic Schools of Germany and Switzerland—that the Commissioners are disposed to attribute the success that has attended the foundation of various large manufacturing industries on the Continent, and they are of opinion that the success would not have been achieved to its full extent had it not been for the system of high technical instruction in these schools, and for the facilities they afford for carrying on the thorough study of those sciences which bear upon industrial art.. These schools are the recognized channel for the instruction of persons who are intending to become the technical directors of industrial establishments, but the German universities also share largely in the training of technical chemists.

The consequence is that the Commissioners have been much impressed with the general intelligence and technical knowledge of the masters and managers of industrial establishments on the Continent. They state that they have found them, as a rule, possessed of a sound knowledge of the sciences upon which their industries depend, familiar with every new scientific discovery of importance and able to appreciate any possible application of it to their special purposes. Thanks also to their knowledge of foreign languages and of the conditions of manufacture prevalent elsewhere they are ready to adopt not only the inventions and improvements made in their own country, but also those of the world at large. Hence the working of their establishments presents a marked contrast to the "rule of thumb" which too often obtains, for instance, in chemical works in this country. Even in respect to the alkali industry, whilst the Commissioners admit that some English makers are as good alkali makers and just as well acquainted with the scientific bearings and relations of their own manufacture as their continental rivals, they consider that the continental alkali makers are men of wider knowledge and of more extended scientific attainments. Thus it is thought that whilst probably none of our English alkali makers could discuss the chemistry of the latest organic colouring matter, nearly all the continental masters are competent to do so. The extent to which the scientific spirit pervades large industrial undertakings on the Continent is illustrated by what the Commissioners saw in their visit to a coal-tar colour works at Basle, which is by no means the largest of its kind. At the head there was a "scientific director," who was a thoroughly educated chemist, and under him, in charge of the main departments, there were three "head chemists," each of whom had been trained in the Zurich Polytechnique, and below them were a number of "assistant chemists," similarly educated. These chemists carried on their investigations respecting the productions of new colouring matters, or the more economical manufacture of old ones, in ten well-equipped experimental laboratories, which were supplemented by a large scientific library. We may refer more in detail on a future occasion to the progress that has been made under these conditions; but it will be apparent that the unfortunate departure of the coal-tar colour industry from this land would require little further explanation. The principal lesson to be drawn from the Report—and one not without its bearing upon the subject of the proper training of the pharmacist—appears to be that a thorough and sound scientific and technical training will be an essential preliminary in the future to the successful carrying on of any great industry. The Commissioners fear that the belief in the efficacy of training of this highest character is at present small in England, although, as they point out, there is no country in which so many abstract investigations have been undertaken that have been afterwards turned to practical account. Still even in England some advance is being made; in many large factories the skilled chemist is already a part of the regular staff, and it may be hoped that the work of the present Commission, the appointment of which was really the expression of a healthier state of public opinion on the subject, may help to add to those qualities which have enabled our countrymen hitherto to keep in the front ranks that amount of scientific knowledge which is indispensable to the intelligent carrying on of their industries.

CINCHONA CULTIVATION IN CEYLON.

In the Annual Report by Dr. Trimen on the Royal Botanic Gardens in Ceylon for the year 1883, he quite confirms a statement that we quoted a few months since as to the unsatisfactory outlook for the once promising and extensive experiment in the cultivation of cinchona by private persons in that island. The interests involved may be estimated from the fact that the export from Ceylon during the last commercial year amounted to nearly seven million pounds of bark. But there has been a large decrease in the number of cinchona plants and Dr. Trimen at the time of writing his report anticipated that the large export would not be maintained, whilst a fear is expressed that a large proportion that had been exported "was very poor stuff," which at the prices then prevailing could hardly have been worth sending home. It is estimated that at the end of the year there were probably 128,000,000 of cinchona plants in Ceylon, of which not more than 22,000,000 were over two years old, and it is thought that the proportion of the other 122,000,000 which would grow up to maturity would prove to be very small. The heavy mortality of seedlings and young trees now experienced in the island has caused much disappointment, and is said by planters to exceed that which obtained formerly. The cause of this mortality has been assumed to lie in a "degeneration" of the cinchonas since their cultivation in Ceylon, each generation being supposed to be inferior in vitality to the one that preceded it. But Dr. Trimen does not see any clear evidence of this, as, under similar conditions, the tendency to die at an early age is as marked in plants grown from seed fresh from South America or the West Indies as in those from Ceylon-grown seed. He considers the cause is to be sought rather in the climate and soil of Ceylon. Much of the shallow soil and cold subsoil and many of the wet, windy and exposed hill sides have proved very unsuitable for cinchona as a permanent cultivation; but in well-protected localities, with a deep soil and good drainage, it is thought probable the plant grows as well now as it ever did in Ceylon. But even under the favourable conditions that might be supposed to be present in the experimental plantations in the Government gardens, the experience cannot be said to be promising, for the manager at Hakgala reports that the plants were dying there at such a rate as to necessitate special replanting, and that although there had since been some improvement, hardly a plant had made satisfactory growth, whilst those of the calisaya class had nearly all died.

The second reading of the Medical Acts Amendment Bill in the House of Commons is set down as the fourteenth order of the day for Thursday. As, however, the Bill is "blocked" by Messrs. Warton and Biggar, there is little doubt that it will again have to be postponed.

* * *

We are requested by the Curator to state that he is desirous of making the Herbarium of British plants belonging to the Museum of the Pharmaceutical Society as complete as possible. He will, therefore, be glad to receive one or two well-dried characteristic specimens of local species or of any of the varieties or forms of critical species. The Curator hopes thus to make the Herbarium valuable for reference to those who will compete for the prizes of the Society, and for those members of the Society who are interested in compiling local floras.

* * *

The *Bulletin Commercial* reports a serious explosion at Constaninople during the preparation of oxygen, which furnishes a fresh demonstration of the necessity that exists for verifying the chemicals used in this operation. It appears that the operator, M. Aliprandi, a pharmacist, having run out of binoxide of manganese, sent for a supply to another pharmacist, M. Alekian, and placed about 125 grams of this material together with an equal quantity of potassium chlorate in a Limousin apparatus made of steel. Having observed that after heat had been applied for two minutes not a bubble of gas had passed through the wash bottle, M. Aliprandi became apprehensive and had barely escaped from the room before an explosion took place, which did a considerable amount of damage. Upon examining the remaining portion of the black powder that had been received as binoxide of manganese it was found to consist entirely of sulphide of antimony. Some question appears to have arisen as to the person upon whom the responsibility for the consequences of supplying one article for another lies, and it is suggested that M. Aliprandi has a remedy against M. Alekian, who also can recover from the French house by whom he was supplied. But it does not appear to us that the question can be settled quite so simply, for if M. Alekian incurred a responsibility by receiving an article into stock without examination, a similar responsibility would lie upon M. Aliprandi himself, who was equally negligent.

* * *

At the meeting of the British Medical Association in Belfast, which is to commence on the 29th inst., there is to be a debate on Indian Drugs in the section devoted to Pharmacology and Therapeutics, which promises to be one of the features of the gathering. On the other hand in the International Medical Congress to commence in Copenhagen on the 10th of August, there is to be no special section for Materia Medica, as it will be remembered there was in the similar Congress in London, and this is described by a medical contemporary as "a most wise decision."

* * *

The Third Annual Meeting of the British Association of Inspectors of Weights and Measures is to be held in Glasgow, in the Christian Institute, on Tuesday and Wednesday, the 24th and 25th of June. Amongst the business that will come before the Association, it is announced that at 1.30, on Tuesday, a paper, by Mr. Shaw, of Edinburgh, will be read, entitled, "Observations on the Weights and Measures of Apothecaries and the Necessity existing for Exactness in Comparing and Verifying the Same." On Wednesday morning, at 10 o'clock, Mr. Gillman, of Leeds, is to read a paper entitled, "A Consideration of the Scientific Laws relating to the Operation of Weighing and to Weighing Apparatus."

* * *

We have received from the Postmaster-General a copy of a notice calling attention to the desirability that bottles containing liquids, intended for transmission by the Parcels Post, should always be firmly packed in tin or wooden boxes, well stuffed with a soft material, special attention being given to the packing round the shoulders of the bottles. Some of the prepared papers specially introduced for the purpose are spoken of as very suitable. When more than one bottle is sent in a parcel, each bottle should be separately wrapped and a wooden division placed between the bottles.

* * *

The luxuriant manner in which many garden plants flourish in the island of St. Helena has suggested the possibility of cultivating flowers there for the sake of extracting the perfume. One difficulty has hitherto been the want of a simple and inexpensive apparatus for the purpose of the extraction, but there now seems to be some probability that it will be overcome. The island was formerly quite a lemon garden, so that many localities bear names associated with the plant, and the lime was also plentiful; but the neglect to provide a fresh set of plants as the older ones died out was so complete that during the last ten years the trees yielding these fruits in the island have become local curiosities.

* * *

At the meeting of the Chemical Society to be held on Thursday evening next, papers will be read "On the Magnetic Rotation of Chemical Bodies in relation to their Composition and Constitution," by Dr. Perkin, F.R.S.; "On the Effect of High Temperatures on Petroleum Hydrocarbons," by Drs. Armstrong and Miller; and "On Nitrification" (Part III), by Mr. R. Warington.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

A meeting of this society was held in the Council Chamber, Church Institute, May 29. The President, Mr. S. Taylor, in the chair.

After the election of five new members, Mr. E. Yewdall read a paper on "The Advantages and Responsibilities of the Retail Chemist and Druggist under Existing Laws."

Mr. Yewdall reviewed the position of the retail chemist for the past thirty years, and gave a historical account of the work done in obtaining the Pharmacy Act, pointing out the similarity of the principal clauses in each of the Bills originally presented to Parliament, with the object of showing that it was not because a more stringent Act had not been sought for, but in consequence of the free trade principles so predominant in the House of Commons, that an Act better suited to the wants of the body of chemists and druggists had not been obtained. He thought the penal clauses of the Bill sufficiently strong to protect the titles of pharmaceutical chemist or chemist and druggist, and maintained that the protection was quite as much as the College of Surgeons was able to offer and such as the public would eventually recognize more fully than is done at the present time. The dealing in scheduled poisons and similar preparations by unregistered persons was considered as demoralizing to the trader, rendering him liable to a conviction with penalties, which, once obtained, would carry its own condemnation; the practice is, moreover, unfair towards pharmacists and fraught with danger to the public. Chemists and druggists should endeavour to improve their position, not by battling with unprincipled men, but in the manner indicated in the eloquent address given by Professor Attfield to the members of the Pharmaceutical Conference last year. Although inconvenience and annoyance have arisen from the practical working of the Weights and Measures Act, yet the advantages consequent upon accuracy in minim measures must be great, as a drop, more or less, of an essential oil in the preparation of a perfume materially alters the product, and in the preparation of medicines containing hydrocyanic acid or the solutions of the alkaloids, accurate uniformity is of great importance. In the graduation of covered pots for ointments, it was thought they would be better adapted for the purpose if olive oil at 60° F. was used instead of water at the same temperature. The practice of a more frequent examinations of the powders received from wholesale houses to avoid being charged with sophistication under the Sale of Food and Drugs Act, would be advantageous to the chemist and druggist in rendering him more familiar with the processes of detection and thus enable him to bring before the Association subjects for discussion. In referring to the depression which has lately affected pharmacy, the author thought the medical profession did not consider the position of the retail chemist as it ought to do; in too many instances a prescription is written for some proprietary article, respecting the composition of which there was either a doubt or the ingredients are so well known that in the interests of the members of the medical profession it was important that a properly written prescription should be given, by which the chemists could prepare the medicine. If this course was not adopted the patient who had found benefit from the proprietary article had no compunction in recommending it to his friend, and thus the medical man lost his fee and the retail chemist his legitimate profit.

The President, in opening the discussion, stated his concurrence with the views held by Mr. Yewdall, and expressed the hope that the Association was about to enter on a more active phase of its existence.

Mr. R. Reynolds desired to express the obligation of the Association to Mr. Yewdall for his historical review of several matters which had much interest for pharmacists during the past few years. He did not expect that any great comfort would be found by those who had no great reason to complain of the condition of pharmacy in England, but it was worth pointing out that this state of things had arrested the opening of new business establishments. Respecting the action of the Pharmaceutical Society, through its Council, in maintaining the existing law against offenders, he could state that it was by no means so inactive as had been often supposed and sometimes publicly asserted. The Society had taken active measures during the past year with regard to several infringements of the Pharmacy Act in Leeds, and it was still ready to investigate complaints as to illicit trading. Mr. Yewdall, as he knew, had always done the Society justice in recognizing what it did, and was himself equally active, as a member of the Executive Committee of the Trade Association, in endeavouring to make the law respected. He (Mr. Reynolds) regarded Mr. Yewdall's paper as peculiarly opportune and a fitting prelude to that call to practical action which might come at any moment, when the promised Bill for the further Regulation of the Sale of Poisons was introduced by the Government. It was to be feared that a Bill to which they could give an unqualified assent would not be presented; it was, therefore, well to be prepared for prompt action.

Mr. Reynolds moved a vote of thanks to Mr. Yewdall for his paper.

Mr. Jas. Abbott seconded the proposition, and alluded to the necessity for accurate measurement by patients of concentrated medicines; he referred also to the considerable variation in the internal capacity of dispensing bottles.

Several other trade topics mentioned by Mr. Yewdall were discussed by the Secretary, Mr. Shillito, and others.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The annual meeting was held at the George Hotel on Tuesday evening. Mr. Councillor Fitzhugh, F.C.S., presiding.

The members present expressed their congratulations to the President upon the honour which had recently been conferred upon him in having been elected by the Lord Chancellor as one of the Justices of the Peace for the Borough.

The Secretary presented the Council's Annual Report, which showed that advance and progress had been made in the work of the society during the past year. Suitable rooms had been obtained for the use of the members and associates. Cases to contain the library and specimens of materia medica had been placed in them, and a number of standard works had been purchased and added to the library, thereby much increasing its usefulness. Twenty-five associates have joined the Society during the past session. Meetings have been held monthly; the associates' meetings having been opened with a conference and *soirée*, both of which were a great success. Lectures have been delivered by Mr. F. H. Spencer, on "The Ear," illustrated by models; by Professor Clowes, D.Sc., F.I.C., on "Spectrum Analysis," of a most able and interesting character and admirably illustrated by Mr. A. H. Simpson with the oxyhydrogen lantern; by Mr. H. Major, B.A., of Leicester, on "Epidemics." During the winter a most successful pharmaceutical chemistry class had been conducted by Professor Clowes at the University College. It continued over two college terms, the attendance of the students the first term being 88 per cent., the second term 77 per cent. At the close the Professor conducted an examination extending over two evenings, at which 50 per cent. of the students passed. There has also been a meeting of the young men every Friday evening at the

Institute rooms. In all, sixteen meetings have been held, with a good and encouraging attendance at each. Members of the Council have been present each evening and presided over the meetings. The discussions have been upon subjects bearing upon the work in which the associates have been engaged during the day. Mr. William Widdowson kindly volunteered to conduct a class on materia medica and pharmacy for those young men who were preparing for the London Minor examination. Those who have had the opportunity of attending bear testimony to the value the lectures have been to them, and the thanks of the Council and Association were given to Mr. Widdowson for his kindness in undertaking this work. The library has been well used by the associates, the number of issues having been larger than in any previous year. The Association has lost by death during the year Mr. J. H. Atherton, F.C.S., a former President, Mr. S. Littlewood, Sutton-in-Ashfield, and Mr. Thomas Harrison, late of Wheeler Gate, all of whom had been members of the Society since its commencement.

A vote of thanks was passed to the Officers and Council of the past year on the motion of Mr. Roberts Jackson, seconded by Mr. Inger.

The ballot for the Officers for 1884 and 1885 was next taken, and resulted as follows:—President, Mr. Councillor Fitzhugh, F.C.S.; Vice-President, Mr. M. H. Humphries; Treasurer, Mr. W. H. Parker; Honorary Secretary, Mr. C. A. Bolton; Council—Messrs. A. E. Beilby, T. B. Fletcher, S. V. Holgate, A. Smith, C. W. Warriner, F. White, J. Wilford and W. Widdowson.

Messrs. R. H. Beverley and J. Lewis were appointed the Auditors.

The Treasurer presented his Annual Financial Statement, which showed the finances to be in a most satisfactory and healthy condition. The expenditure had been £53 13*s.* 5*d.* Income £73 5*s.* 10*d.* The balance, including amount on deposit in the bank, reaches £73 3*s.* 8*d.*

The prizes kindly offered by Mr. J. H. Haywood, of £1 1*s.*, and Mr. A. Middleton, of 10*s.* 6*d.*, at the commencement of the session, not having been able to be competed for by the associates at an examination, were allowed to stand over until next session.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Sunday, May 25, the members of the above Association, with a few friends, took a botanical ramble in the neighbourhood of Marple, Cheshire. The facilities afforded by the district of Oldham for the practical study of botany are exceedingly few, as for miles around are nothing but cotton mills and iron-works, etc.; this being the case, those who wish to study botany from fresh specimens are obliged to travel many miles to meet with anything like a fair amount of vegetation. This was the object of their journey, and a large store of spring flowers for study was gathered.

On Tuesday evening, at the usual weekly meeting of the Association, held in their room, Church Institute, the numerous plants gathered on Sunday were classified, each plant being placed in its natural order, its peculiarities of structure, mode and place of growth being noticed.

MANCHESTER PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held in the Materia Medica Museum, Owens College, on Thursday evening, May 22. Mr. A. H. Jackson, B.Sc., President, in the chair.

The minutes of the previous meeting having been read and confirmed, the Chairman called upon Mr. A. D. Breeze, to read a paper on "The Poisons Question—Is Legislation Necessary?"

The author, having quoted Sections II. and XVII. of the Pharmacy Act, 1868, gave a very interesting summary of the existing grievances relating to the retailing of poisons and sale of patent medicines of a poisonous nature, suggesting that the infliction of a heavier penalty than that now prescribed by the Act would prove beneficial in discouraging the illegal sale of poisonous drugs.

The paper was followed by a lengthy discussion in which the Chairman, Messrs. Elborne, Thornley, Mitchell, Rhodes, Thomas and Kirkby, took part; and the following resolution, proposed by the Secretary, was carried by the majority of members present:—"That all poisons sold as 'vermin killers' should be classed in Part I. of the Poison Schedule, unless labelled as not containing any of the poisons mentioned therein.

The Chairman then called upon the Secretary to read a letter which had been received from the manager of Messrs. Tennants and Co., inviting the members of the Association to inspect their large chemical and sulphuric acid works, at Ardwick Green. It was resolved that the kind invitation be accepted.

The Secretary then read a letter from Mr. James Hart, of Embden Street, Manchester, expressing his pleasure that a Pharmacy Students' Association had been formed in Manchester. This, he thought, was a move in the right direction, and augured better for the "future of pharmacy" than anything that had yet taken place there. As one who took great interest in the future welfare of the trade, he was prepared to offer as an incentive an annual prize of one guinea for competition amongst the members of the Association, for the best collection of plants found within a given radius of Manchester, or to be devoted to the furtherance of pharmaceutical research in any way which the Committee might consider expedient.

It was unanimously resolved to accept Mr. Hart's kind offer, the best mode of awarding the prize being referred to the Committee for consideration.

The next meeting will be held on Thursday evening, June 19, at 8 p.m., when a paper will be read by Mr. J. Brooks Thornley on "Sulphuric Acid Manufacture."

On Saturday afternoon, May 24, at the Botanical Gardens, Old Trafford, Mr. William Elborne (Assistant-Lecturer on Materia Medica, Owens College) delivered an interesting lecture on "Botany," to a social gathering of members of the above Association. The lecturer gave a general sketch of the characters of the various classes and divisions of the vegetable kingdom, and described in a very lucid manner the organs of nutrition and reproduction, their individual functions and structure. There was a good attendance, the consensus of opinion being that a most enjoyable afternoon had been spent.

HAWICK PHARMACEUTICAL ASSOCIATION.

The annual meeting of this Association was held on Tuesday, June 3. There was a good attendance, and Mr. Maben (Hon. President) occupied the chair.

After a few introductory remarks by the Chairman, the reports of the Secretary, Treasurer and Librarian were submitted. From these it appeared that the Society was in a good condition in every respect.

The following office-bearers were elected for the ensuing year:—Hon. President, Mr. John Craig; President, Mr. Lawson; Secretary, Mr. J. A. Hislop; Treasurer, Mr. T. Maben; Librarian, Mr. W. B. Rawlinson.

It was moved and carried by a majority that the name of the Association be altered to "The Hawick Pharmaceutical and Chemical Association," and the constitution was amended so that all past and present science students would be eligible for membership.

It was resolved to apply to the Committee of the

British Pharmaceutical Conference for a copy of the 'Year-Book of Pharmacy.'

It was agreed to issue a syllabus for next session, for which a number of papers had already been promised, and also to have botanical excursions instead of in-door meetings during the summer months.

After the business had been disposed of, Mr. Dechan, chemist, showed and explained a large collection of apparatus as used in analysis. Amongst these was a novel arrangement for filtering at the boiling point, the idea of which was taken from an apparatus for a similar purpose figured in a recent number of the *Journal de Pharmacie et de Chimie.*

A herbarium of the flora of the district was on view, and the Hon. President described the method of collecting, drying and mounting specimens.

It may be stated that the Secretary's report referred to the fact that the Association had commenced to form a herbarium of the local flora; this has already made considerable progress, a number of plants connected therewith being on the table.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, June 5. Dr. W. H. Perkin, F.R.S., President, in the chair.

It was announced that a ballot for the election of Fellows would take place at the next meeting of the Society, June 19.

The following certificates were read for the first time: —F. Broughton, F. J. Down, F. G. Holmes, J. Hulme, C. Thompson, W. F. Wyley.

Mr. C. E. Groves then read a paper—

On β-Naphthaquinone.—In a preliminary notice read before the Society some time back (*Chem. News.*, xliii., 267) the author mentioned that he had carefully repeated some experiments of Liebermann, but could not agree with him as to the value of β-naphthol orange as a source of β-naphthaquinone. In the present paper, full details are given of the preparation of amido-β-naphthol hydrochloride from the β-orange, by reduction with stannous chloride and with alkaline sulphides. Although this reaction is interesting theoretically it is far inferior in simplicity and economy to the process originally proposed by Stenhouse and the author (*Jour. Chem. Soc.*, 1877, ii., 47, and 1878, *Trans.*, 415), which consisted in preparing nitroso-β-naphthol from β-naphthol by the action of nitrosyl sulphate and then reducing the barium derivative by ammonium sulphide. As sodium nitrite is prepared now on the large scale almost pure, the author has substituted for the nitrosyl sulphate, a mixture of sodium nitrite and dilute sulphuric acid; the sodium nitroso-β-naphthol is then introduced in the moist state into a solution of stannous chloride and hydrochloric acid and thus converted into amido-β-naphthol, a large excess of stannous chloride being avoided. The author prefers the use of ferric chloride to convert the amido derivative into the quinone. This process is much simpler and cheaper than the method proposed by Liebermann. Nitro-β-naphthaquinol $C_{10}H_5NO_2(HO)_2$— In a former paper it was mentioned that this body, together with the amido-β-naphthaquinol, was obtained by the action of hydriodic acid and phosphorus on the nitroquinone. These bodies can be more conveniently prepared by the employment of stannous chloride as the reducing agent. In conclusion the author draws attention to the fact, that, although he had, in a paper published in conjunction with the late Dr. Stenhouse, mentioned the production of amido-β-naphthaquinone by the action of reducing agents and more recently had stated in the *Berichte* that he was engaged in an investigation of nitro-β-naphthaquinone and the products obtained from it by the action of reducing agents, yet a student of Professor Liebermann's has recently published a note in which he describes the reduction of nitro-β-naphthaquinone to amido-β-naphthaquinone without the slightest reference to its having been already done.

The two following papers were then read by the Secretary:—

On a Bye-Product of the Manufacture of Aurin (Part II). By A. Staub and Watson Smith.—In a previous paper it was shown that the product in question, phenylorthooxalic ether, was formed by the direct union of two molecules of phenol with one of anhydrous oxalic acid. The authors have prepared a perfectly pure specimen by repeated recrystallization from glacial acetic acid, and an analysis agrees with the formula $C_{14}H_{14}O_6$. Analogous compounds with α and β naphthols have been obtained, but no corresponding body could be obtained with resorcinol. The melting point of the phenylorthooxalate was found to be 126°–127°. When heated with strong sulphuric acid, aurin is obtained. If phenol be present the yield of aurin is not increased. Only traces of formic acid are evolved during the reaction. The authors conclude that the orthophenyloxalate plays no part as an intermediate product in the formation of aurin. They also prove that not a trace of aurin is formed by the action of nascent carbon dioxide on phenol.

On Calcium Hydrosulphides. By E. Divers and Tetsukichi Shimidzu, of Tokio.—One part of lime prepared by igniting precipitated calcium carbonate is made into a thick paste by mixing with four parts of water, hydrogen sulphide is passed through, the lime gradually dissolves, more lime is added, until a solution of the hydrosulphide strong enough to crystallize when cooled is obtained. The preparation of such a solution may take several days. Air must be completely excluded and the process is facilitated by cooling. The solution having been prepared is allowed to settle at a slightly warm temperature, so that any crystals which have formed may be dissolved, and then decanted in an atmosphere of hydrogen sulphide. On cooling, colourless prismatic crystals of $Ca(HS)_2, 6H_2O$ separate out. They are very soluble in water and alcohol; decompose when heated and when exposed to the air. Analyses are given proving the above composition. When this substance is treated with water and calcium hydrate, calcium hydroxyhydrosulphide is formed, $CaHSHO,3H_2O$. This body crystallizes in colourless four-sided prisms, slowly evolving hydrogen sulphide when exposed to the air. By gently heating the hydrosulphide in a current of hydrogen sulphide, calcium monosulphide mixed with some hydroxide was obtained as a white amorphous solid. Carbon dioxide decomposes the calcium hydrosulphides, and the authors find that hydrogen sulphide decomposes calcium carbonate, so that carbon dioxide mixed with an excess of hydrogen sulphide may be passed through lime water without causing a turbidity. Odling states that when calcium hydrosulphide is boiled with sulphur, hydrogen sulphide is liberated; calcium pentasulphide is formed under these circumstances. The authors show that hydrogen sulphide bubbled through a cold dilute solution of pentasulphide effects the reverse reaction, and reforms the hydrosulphide. In conclusion, the authors have investigated the formation of thiosulphate from the hydrosulphide and the pentasulphide, and they conclude that in both cases it is not a direct oxidation, but that the hydrogen sulphide oxidizes, and then by the reaction of its products forms the thiosulphate. They give the following equations:—

$$CaHSHO + 2O_2 + HS_2 = CaS_2O_3 + 2H_2O$$
$$CaS_5 + 2H_2O = CaHSHO + 3S + H_2S.$$

The hydrosulphide then reacts with oxygen and the hydrogen sulphide as above.

The Society then adjourned to June 19, when a ballot for the election of Fellows will be held, and the following papers read:—"On the Magnetic Rotation of Chemical

Bodies in relation to their Composition and Constitution." By W. H. Perkin, F.R.S.; "On the Effect of High Temperature on Petroleum Hydrocarbons." By Drs. Armstrong and Miller; "On Nitrification," Part III. By R. Warington.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, May 29, Mr. H. G. Greenish, Vice-President, in the chair.

The first paper read consisted of some notes on—

ASAFŒTIDA.

BY R. W. C. PIERCE.

The name asafœtida is derived from the Arabic "asa," healing, or "isa," remedy, and the Latin "fœtidus," fetid. The botanical source of asafœtida is now generally attributed to two large umbelliferous plants, *Ferula narthex*, the *Narthex asafœtida* of Falconer, and *Ferula scorodosma*, or the *Scorodosma fœtidum* of Bunge. *Ferula narthex* was discovered by Dr. Falconer in 1838 on the northern slopes of the mountains dividing Kashmir from Western Thibet, seeds of which he sent to the Edinburgh Botanic Gardens, where they germinated and produced a plant which flourished for several years, but died after flowering. Plants more or less allied, and also said to afford asafœtida, have been met with in Herat and Afghanistan. *Ferula scorodosma* was collected in 1841 by Lehmann on the east side of the sea of Aral, and also in Bucharia. It probably extends over a wide district of Turkestan, Northern Afghanistan and Eastern Persia. Whether this plant is the *Ferula asafœtida* of Linnæus cannot be certainly decided. There is no doubt that the drug is afforded by other allied species of *Ferula* besides the two previously mentioned. The *Ferula asafœtida* of Bunge, now called *Ferula alliacea*, yields asafœtida, which is known in the Bombay market as "Hing" at the present day. Asafœtida is, according to Flückiger and Hanbury, the produce entirely of Afghanistan, but, according to Dr. Dymock, it is also produced in the province of Laristan, in Persia. The drug is forwarded to Bombay principally by way of the Persian Gulf. The asafœtida which comes from Southern Persia is supposed to be derived from *Ferula scorodosma*, and that from Afghanistan is supposed to come from *Ferula narthex*. This latter plant, however, has never been found by anyone except Falconer for certain, and by him only in Thibet, hence the botanical source of the Afghanistan asafœtida is merely conjectural. The consumption of asafœtida in Europe, America and other places is small in comparison with the amount used in Persia and India, where it is known as "Hingra." Asafœtida was known to the Arabians and Persians of the middle ages, who mention two kinds, one good, or sweet, the other fetid. In the 13th century the Meddygon Myddfai, or physicians of Myddfai, considered it as one of the substances which every physician ought to know and use. It constitutes a favourite seasoning for food with the inhabitants of many parts of the East. The Indian Banians, who never eat animal food, use it in almost all their dishes and before their meals; even rub their mouths with it in order to stimulate their appetite. It is sometimes used by our own cooks, but in very minute quantity, in place of garlic. In many parts of Arabia and Persia it is much esteemed as a remedy for various internal diseases and as an external application to wounds. With us it is considered a powerful medicine in several disorders. It has been applied with suceess in the cure of whooping cough and worms, and in flatulent colics. The part of the plant from which the drug is obtained is the root, in which, after it is four years old, incisions are made. The upper part of the root, which is sometimes as thick as a man's leg, rises somewhat above the surface of the ground. When cut, the asafœtida exudes in the form of a white thick juice like cream, which, from exposure to the air, becomes at last of a dark brown colour. It is very apt to run to putrefaction, and hence those who collect it carefully defend it from the sun. The fresh juice has an excessively strong smell; a single drachm of it is said to smell more than a hundred pounds of the dry asafœtida brought to us. The harvest commences when the leaves begin to decay, and the whole gathering is performed by the inhabitants of the place by four different journeys to the mountains. The quantity yielded by a root varies from half an ounce to two pounds. The product got from the first cutting, which is thinner, more milky and less esteemed than that obtained afterwards, is not sold in its natural state, but is mixed with soft earth, which is added to the extent of an equal, or even double, weight of the gum resin, according to the softness of the latter. It is stated that a single ship is exclusively devoted to transporting the bulk of the drug to ports in the Persian gulf, and that when smaller parcels are carried it is usual to tie them to the top of the mast.

As found in the shops asafœtida is in irregular masses, softish when not long exposed, of a yellowish or reddish-brown colour, externally, exhibiting when broken an irregular whitish, somewhat shining surface, which soon becomes red on exposure and ultimately passes into a dull yellowish brown. This change of colour is characteristic of asafœtida, and is ascribed to the influence o air and light upon its resinous ingredient. The massef appear as if composed of distinct portions agglutinated together, sometimes of white, almost pearly tears embedded in a darker, softer and more fetid paste. It is rarely met with in separate tears, which are roundish flattened, oval or of irregular shape, from the size of a pea to that of a large almond or larger, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odour, which, however, is weaker than that of the masses, to which latter they are considered inferior. A very fine variety of asafœtida is said to be obtained from the leaf-bud in the centre of the root. It is known in the Indian bazaars as kandahari hing, but it is not found in European commerce. It occurs in moist flaky pieces and tears, yielding a reddish-yellow oil on pressure and mostly mixed with the remains of leaf-buds. Asafœtida has a powerful but not purely alliaceous odour and a bitter acrid and durable taste. It becomes harder and more brittle by keeping and also diminishes in smell and taste It softens by heat without melting, and is difficult to powder. According to Berzelius its specific gravity is 1·327. I have taken the specific gravity of two specimens, one being 1·2 and the other, which we shall see further on contains a very large amount of adulteration, being 1·7. It is inflammable, burning with a clear lively flame. It yields all its virtues to alcohol and forms a clear tincture which becomes milky on the addition of water. It forms a whitish or pinkish-white emulsion with water. When rubbed up with sulphuric acid in a mortar, then diluted and the solution neutralized by ammonia, the then slightly coloured solution exhibits a bluish fluorescence, which is due to the presence of umbelliferone. Touched with nitric acid, specific gravity 1·2, the tear becomes of an evanescent green colour. The asafœtida of commerce has been shown to be always more or less impure. The common impurities are stones, sand, powdered gypsum and wheat or barley flour, mixed in varying proportions according to the consistence of the gum resin. At Bombay it is further adulterated, frequently by opening the packages and mixing it with gum arabic.

Asafœtida consists of resin, gum and essential oil in varying proportions. The proportion of oil varies from 3 to 9 per cent. the gum from 26 to 32 per cent, and the resin from 47·2 to 65 per cent. The resin is almost entirely soluble in alcohol, ether, and chloroform, it dissolves without decomposition in warm concentrated nitric acid. It contains a little ferulaic acid. Fused with caustic potash it yields resorcin, and by distillation oils of a green, violet or red tint, besides about ¼ per cent. of umbelliferone, $C_6H_9O_3$. The mucilaginous matter of asafœtida consists of a gum soluble in water and an insoluble portion which is bassorin. The volatile oil has a light yellow colour, with a very repulsive odour. It is at first neutral, but on exposure becomes acid and acquires a different odour. It contains from 20 to 25 per cent. of sulphur, and on being distilled evolves sulphuretted hydrogen.

"Hing," the medicinal asafœtida of the natives of India, obtained from *Ferula alliacea*, consists of 37·50 resin and essential oil, 23·75 of gum. It may be distinguished from commercial asafœtida by not yielding a fluorescent solution, by its tincture not being precipitated by acetate of lead and by containing slices of roots, stem remains only being found in ordinary asafœtida, whilst the alcoholic tincture of the latter is precipitated by acetate of lead.

In the British Pharmacopœia the test for asafœtida is that it dissolves almost entirely in rectified spirit. As there is from 26 to 32 per cent. of gum this cannot be true, without taking into account impurities which are always present. According to the United States Pharmacopœia it is partly soluble in ether, and at least 60 per cent. of it should dissolve in alcohol of specific gravity ·820, containing 91 per cent. by weight of C_2H_5HO. The German Pharmacopœia gives the following characters:—"It gives a yellow colour with caustic soda. Does not strongly effervesce with hydrochloric acid, and is not coloured by contact with the acid for six hours. It should not leave more than 10 per cent. of ash." I have worked a little upon these tests with the following results:—

No. 1. Tear asafœtida yielded 5 per cent. of ash and yielded 56 per cent. to s. v. r.

No. 2. Lump asafœtida yielded 56 per cent. of ash and yielded 26 per cent. to s. v. r.

No. 3. Lump asafœtida, specific gravity 1·77, yielded 56 per cent. ash and yielded 26 per cent. to s. v. r.

No. 4. "Strained" asafœtida yielded 25 per cent. ash and yielded 50 per cent. to s. v. r.

No. 5. Lump asafœtida, specific gravity 1·2, yielded 12 per cent. ash and yielded 54 per cent. to s. v. r.

They all gave the NaHO reaction and the fluorescence, but they were all coloured of a greenish blue by HCl almost immediately. Nos. 3 and 4 are very impure, heavy, and have a sandy appearance.

The samples were obtained from different wholesale and retail houses, and from the Society's Museum.

Some years ago Professor Maisch, of Philadelphia, published the result of his analyses of several samples of asafœtida taken by the drug inspector of the port from different cases and from different parts of the mass. It was as follows:—

	1.	2.	3.	4.	5
Total resin and volatile oil . .	36·48	43·89	62·93	39·48	30·08
Impurities . . .	57·50	44·01	15·20	51·70	62·09
Gum, moisture and loss	6·02	12·10	21·87	8·82	7·83
	100	100	100	100	100

These were samples of amygdaloid asafœtida which a year previously were rejected by the purchaser as adulterated, he claiming that good asafœtida should be entirely free from sulphate of lime. The impurities in the above instance consisted of gypsum and vegetable fragments, as always met with in the resinous matter agglutinating the tears.

Dr. Dymock, in his 'Materia Medica,' states that asafœtida of an ordinary commercial quality in tears yields at least 7 per cent. residue to petroleum ether, lump at least 5 per cent., and that the volatile constituents should not be less than 5 per cent. in tear or 3 per cent. in lump asafœtida.

In the French Codex a "purified asafœtida" is included, and which is directed to be prepared as follows:—

Dissolve the gum resin with heat in a sufficient quantity of 60 per cent. (by volume) alcohol, strain and press, drive away the alcohol by evaporation over a water-bath until the product is sufficiently thick, that when a few drops are thrown into cold water they have enough consistence to work up between the fingers without adhering to them.

A discussion ensued, in which the Chairman, Messrs. Cullinan, Dymond, Lowe and Short took part.

The Reporter on Inorganic Chemistry, Mr. A. J. G. Lowe, then made a report on the "Purification of Crude Antimony Sulphide." This paper will be published in a future number of this Journal.

In the discussion that followed, the Chairman, Assistant-Secretary, Messrs. Cullinan, Dymond and Ince took part.

The Assistant-Secretary announced that at a meeting of the Executive Committee a grant from the Research Fund had been made to Mr. R. A. Cripps for the examination of commercial concentrated infusions and decoctions.

The meeting then adjourned.

INTERNATIONAL HEALTH EXHIBITION.

Conferences on Sanitary Subjects.

The third of the series of Conferences held under the auspices of the Mansion House Council on the "Dwellings of the Poor" was held on Friday, June 6, in the Conference Hall of the Exhibition. Cardinal Manning in the chair.

The first paper read was by Mr. Shirley F. Murphy, M.R.C.S., entitled "Some Difficulties of Sanitary Administration in the Metropolis." He stated that health was everywhere deemed of less importance than mere pocket interests, and, even if people held no higher view of health and life than their pecuniary value, they would be acting wisely in making some sacrifices for their preservation. The only thought which had controlled the arrangement of houses upon a site was for the convenience of traffic and not for the health requirements of the inhabitants. It was not until the year 1855 that London insisted upon the preservation of open spaces at the back or side of the houses which were covering the land, and not until 1862 that the height of a building was held to have any relation to the need for ventilation, and even then only to buildings about be erected in new streets of less than 50 feet in width. To existing streets this provision did not apply, and high, back to back, unventilated houses were permitted on all sides. In 1882 some advance was made, the amount of space in the rear of houses was to have some relation to their size, and for new houses built upon land not previously occupied in whole or in part, before the passing of the Act, an open space equivalent to a strip of little more than 10 feet, continued in proportion to the width of the house, was deemed necessary, and frequently requiring this open space to extend across the whole width of the house. It was true, London possessed sanitary authorities, but it was only after houses were erected and the inhabitants had suffered ill health or lost their lives, that the authorities had power to act. At the present time, the sanitary authorities existed rather for the removal of nuisances than for the prevention of disease. The reason that there had been so little thought for health in the government of the Metropolis was to be found in the difficulties attendant upon the government of London. For years there had been a tendency to place upon central boards duties which should be entrusted only to a body appointed as guardians of the public health. After referring to the difficulties with which sanitary administration was surrounded, he concluded by saying, that at present, no sanitary administration deserving of the name could be said to exist; the local sanitary authorities had no jurisdiction over many subjects of vital importance to the public health, and the authorities upon whom these duties devolved were not primarily concerned in the prevention of disease.

The next paper, by Dr. B. A. Whitelegge, was upon the same subject. After speaking of the evil effects of overcrowding and bad drainage, he said, in the laws bearing upon metropolitan sanitation, there were many important omissions, but still it was none the less incumbent upon the sanitary authorities to faithfully exercise the powers entrusted to them alone, and to their default in so doing many of the present evils were attributable. Repeated and careful inspection of tenement houses was necessary, and the absurdity of alloting to one man a district with a population of 50,000 or 60,000 was obvious. With the sanitary authority rested the responsibility of taking the initiative in active measures, but in many cases it was reluctant to do so, as all sanitary action meant expense, and short-sighted economy too often interfered with due care for the public health. Much might be done by individual and collective action in organizing public opinion. The poor should be educated as to the vital importance of healthy homes and surroundings, and the means by which unhealthy conditions might be avoided or remedied. The attention of the authorities should be called to all unhealthy conditions which could be found, and care be taken that the evils so reported were remedied. A great deal had been done in this direction by the thirty local sanitary aid committees, formed in connection with the Mansion House Council on the Dwellings of the Poor, over five hundred cases having been inquired into, and in all cases brought before the Committee the utmost secresy was observed as to the quarter from which they received information.

The third paper, by Mr. C. M. Sawell, was entitled "Suggestions to the Royal Commissioners on the Dwellings of the Poor," and proved a somewhat lengthy document. The first suggestion was that no immediate transformation in the condition of the poor could be expected, and that their character needed improvement above all things. Next, it was suggested that the housing of the poor had become a practical monopoly, and various instances were given of the exorbitant rents charged for the vilest accommodation. Thirdly, the system of leases was remarked upon as having a tendency to accentuate the evils complained of, and a suggestion was made that some draconic powers should be given to municipalities to acquire property without paying excessive compensation. Next came some remarks on the land question generally, and the remaining suggestions dealt with the licensing question, the registration of inspection of all houses let out in lodgings, the disqualifying owners of unsanitary property for local offices, the extension of the hours during which common lodging houses may be inspected, Government loans to aid in reconstruction, a reduction of rates on "improved dwellings," and the enforcement of cheap railway accommodation.

Dr. Alfred Carpenter said the practical side of the question bristled with difficulties, one being the antagonism which existed between local self-government and centralization. This difficulty had been enhanced to a great degree by legislation, and therefore they must go to Parliament to get it removed. Another difficulty was that the exigencies of political life prevented arrangements which were made from being carried out. A Commission appointed to inquire into infectious hospitals in connection with London, of which he was a member, recommended the necessity of the separation of sanitary work from that connected with the destitution of the Metropolis, but this proposition had not yet been carried out. He thought it was only by meetings, such as the present, that pressure could be brought to bear upon those on whom hope depended.

The Rev. G. M. Murphy suggested that as speedily as possible the Mansion House Council should call a conference of *bonâ fide* working men; also that there should be a unification of the sanitary laws, and simplicity and promptitude in action.

The Rev. S. Buss suggested that the Artizans Dwellings Act, the Nuisance Removal Act, and various other Acts should be consolidated and amended, and that the building of houses should be entrusted to a department of the State.

The Rev. G. W. McCree thought that if sanitary inspectors were made independent of the body by whom they were appointed, they would do their duty better, not having the fear of dismissal before them in the event of taking action in certain cases.

The Chairman said he thought the proposal that labouring men should become their own landlords was a very good one, and he would always do, as he had hitherto, his best to encourage it. At present the great block buildings housed artizans and even clerks in the city, failing altogether to reach the very poor for whom they were intended. On the Statute Books would be found Acts to meet every case, all that was wanted was a dynamic power to set them in motion, and this power would be obtained from societies like the Mansion House Committee.

On Monday the first of a series of Conferences, under the combined management of the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Parkes Museum of Hygiene, was held, under the presidency of Dr. Orme Dudfield, President of the Society of Medical Officers of Health and Medical Officer of Health for Kensington.

The first paper was by Dr. Tripe, Medical Officer for South Hackney, on "The Domestic Sanitary Arrangements of the Metropolitan Poor." The word "poor" was used in its largest sense, as including all who live in very small houses or tenements. The writer said the sanitary arrangements of many of those houses were disgustingly defective, and owing to the dirty habits of many of the inhabitants, even fairly good water closets were so misused as to convert them into the most filthy places it was possible to conceive. Persons of this class could scarcely be said to have any sanitary arrangements whatever. Another class of houses, those containing five or six rooms, in which two or more families lived, were somewhat better, and in such houses the enforcement of the regulations made under sec. 35 of the Sanitary Act was of great service. The difficulty was, however, that if inspection were very frequent, and the owners put to much expense, the rents were increased, and the tenants as a consequence, ejected, to carry a bad example elsewhere. On the other hand, if due regard were not paid to sanitary arrangements, disease might arise and spread. The opinion was expressed that the Peabody and similar buildings were not so suitable for the very poor as smaller houses with outbuildings. The most important of sanitary arrangements was the water supply, and a constant supply was much preferable to an intermittent one; there should always be a cistern which would supply the closet, but the water for potable purposes might be drawn from the main before it reached the cistern. Where the constant system was not in operation there should always be a flushing box between the cistern and the closet, and great care must be exercised to see that this flushing box was properly arranged and fixed, or it would be rendered useless. The different kinds of taps, etc., in use under the constant system were then discussed, many complaints being made of the time required in some cases to draw a pail of water. A direct connection between the sink and the sewer was a fruitful source of mischief from the influx of sewer gas. The heads of rain-water pipes often opened near windows, and when connected directly with the sewer acted in the same way as conductors of foul gases. The drainage of old houses was often very defective, being constructed of bricks with open joints; all such drains should be relaid in pipes laid in concrete. Dustbins were usually a source of discomfort and often of disease; when made of wood they were frequently destroyed, and strong sheet iron was much preferable. The practice of asking for gratuities when the dust was removed was a great check on the frequent emptying of the dustbins, and where the removal was contracted for at a lump sum it was the interest of the contractor to remove it as rarely as possible.

The next paper, by Mr. Ernest Turner, F.R.I.B.A., was on "The Improvement of the Sanitary Arrangements of Metropolitan Houses." He thought the real problem was the sanitary housing, not of the artizan, but of the labourer, and, in order to solve it, they must face its conditions as they arose, and not invent them. The most inexorable of these conditions was just the one which many had hitherto devoutly refused to accept. The labourer had to live in one room, and it was no good endeavouring to persuade him that he could occupy more, as he could not afford more than 3*s.* 6*d.* to 4*s.* a week, and for this sum only one room could be obtained. The introduction of common kitchens and dormitories either undivided or divided into cubicles was a question well worthy of the consideration of the new Royal Commission. Common lodging-houses were by far the most sanitary of any dwellings of the poor, owing to systematic inspection, and if model lodging-houses were constructed to look a shade less like model prisons they would be regarded with more favour by the poor. Upon the question of sanitary fittings he strongly endorsed Dr. Tripe's views as to the supreme advantage of absolute simplicity. He drew attention to plans of a block of buildings recently erected in Westminster, which were admirably constructed in every way,—the soil pipes outside the buildings, and properly ventilated,—and yet paying more than 7 per cent. A very important improvement in the construction of these rooms was the character of the partitions formed of corrugated sheet iron covered with plaster, a specimen of which was exhibited. These partitions are only two inches thick, thus saving space, and they were believed to be fire-proof, owing to the addition of sulphur to the cement, and would be readily disinfected. The most common defects, from a sanitary point of view, were next referred to briefly, all of which might be seen illustrated in the model of the unsanitary house in the Exhibition, whilst the sanitary house by the side would show what the corresponding arrangements should be. Old houses, though usually defective, would often stand pulling about a little better than new ones, and one thing, the most necessary, could always be done, viz., disconnecting the drains by interposing a water-trap and communication with the fresh air between the sewer and the house; waste pipes should also be made to discharge in the open air, and the water cistern rendered easily accessible, properly covered, and cut off from all communication with the drains.

Mr. Rogers Field emphasized the importance of means of attending to the water supply of the cistern being readily accessible, and of effective flushing apparatus for closets. He did not expect to find any house free from sanitary defects if built more than ten years, and many of those now being built were equally defective. London not being under the Public Health Act, 1875, the immense number of houses constantly being built in the metropolitan district were not properly under control; though in many cases proper arrangements were cheaper than bad ones, they were too often neglected. The only two instances in which he had been interfered with by the sanitary authorities were to prevent his constructing ventilating man-holes.

Professor Corfield drew attention to the importance of dustbins being frequently cleansed and all refuse removed. Some years ago contractors had large sums for the dust and were therefore anxious to get it; now the system was reversed and therefore the only way to insure its regular removal was for the sanitary authorities to undertake the work themselves. The most common defect in London houses was the connection of the water cistern with the drain or sewer.

Dr. Alfred Carpenter agreed with Dr. Corfield as to the removal of dust, and said it was also important that the quantity of dust should be kept as small as possible by improved fire places and the use of gas for cooking and heating. He also recommended frequent visits to the Parkes Museum, Margaret Street, where the best appliances of all kinds, both with regard to drainage and water supply, might be seen.

Dr. Bartlett, in the course of his remarks, alluding to the danger from fire in large blocks of buildings, unless they were thoroughly fire-proof, said from some experiments he had made with cement with which sulphur had been incorporated he believed it would be very valuable in enabling it to stand both fire and water.

Dr. Bernays, spoke of the good quality of London water as supplied by the companies before it got contaminated in the cisterns and said that much of the dustbin nuisance would be removed if vegetables were more carefully prepared before they were supplied to the consumer.

Mr. John Slater referred to the importance of a damp course and of ventilating under the ground-floor, and also advocated iron pipes for drains under houses.

The second of this series of Conferences took place on Tuesday, Captain Douglas Galton, R.E., C.B., F.R.S., in the chair.

The first paper read was on "Domestic Sanitation in Rural Districts," by Dr. George Wilson, Medical Officer of Health, Mid-Warwick District. Dr. Wilson's paper dealt with the questions of labourers' dwellings, water supply, and the disposal of refuse. On the first point he quoted an estimate based on the report of the Agricultural Commission of 1867, that one-third of the rural homes of England were unfit for human habitation, and that, therefore, 700,000 hovels ought to be pulled down. In many villages with which he was acquainted 10 to 15 per cent. of the cottages only contained one sleeping room and about half only two; though in that district, viz., Warwickshire, the defects were, according to the report of the Commission, much less glaring than in many other counties. Many of these defects could be dealt with under the Public Health Act, but a do-nothing policy was often encouraged by the appointment of officers of health at merely nominal salaries. Where they were precluded from engaging in private practice the improvement had been very marked, and the evil was diminished by the decline of the rural population. One of the great obstacles to improvement lay in the poverty of the owners, and another in the low wages of the occupiers, which prevented their paying rents which would encourage private enterprise in building cottages. Another impediment to improvement was the fact that unless the sanitary authorities applied for urban powers they had no control over the erection of new cottages, and thus jerry-building of the worst description and total absence of sanitary appliances were liable to occur. Thus even in the case of country mansions the cesspool was often in close proximity to the well, the drains leaky and unventilated, and the drinking water cistern connected with the water-closet. There was, therefore, a need for further powers and adequate bye-laws. The defects of water supply were next dealt with, and the provisions of the Public Health (Water) Act shown to be in most respects adequate to meet the case, if only they were put in force. The remainder of the paper was devoted to the three important points of closet accommodation, scavenging, and drainage. The old-fashioned privies and cesspools should be converted into pail or ash-pit closets, the contents of which should be frequently removed and put on the gardens, and this could be done at very small expense. The great desideratum was to keep the excreta dry and prevent undue accumulation. Where the garden space was insufficient to receive the excreta due provision should be made for removing it at frequent intervals, and this might be accomplished under the Public Health Act. This still left the slops and refuse water to be disposed of, and in villages and places where the population was increasing, covered drains ought to replace the open gutters and the sewage treated by irrigation if there were any danger of its flowing into streams from which the water supply was derived.

The second paper, on "Sanitary Houses for the Working Classes in Urban Districts," by Mr. H. P. Boulnois, was mainly occupied with technical details of construction which should be attended to in workmen's dwellings. Huge block-buildings were considered to be undesirable, though sometimes from the great value of land they were the only means of bringing decent accommodation within the reach of men earning small wages. Basement rooms were condemned, and flat roofs recommended as affording a drying ground or garden, and a means of escape in case of fire. A narrow street at the back was desirable as a means of removing the refuse daily, and all main streets should be at least forty feet wide. The water supply should be constant, and if intermittent the greatest care should be taken in the construction and fitting of the cistern. The principal obstacles in the way of erecting such dwellings were: 1. The avarice of the builder. 2. The ignorance of both builders and tenants. 3. The want of sufficient supervision by the sanitary authorities, mainly owing to a deficiency in the staff.

Sir Henry Acland, Bart., M.D., in opening the discussion, pressed the necessity of relying more upon the general education of the people than upon compulsion for improving sanitary conditions. He also pointed out the necessity of studying economy in the matter.

Sir Robert Rawlinson, C.B., also dwelt principally in his remarks on the necessity of greater economy in carrying out sanitary works, saying he was often shocked at the exaggerated estimates which came before him, and also at the great expense incurred in arbitrations arising out of sanitary improvements.

Dr. Thursfield remarked on the difficulty of carrying out the provisions of the Public Health (Water) Act owing to the limit of expense which could be incurred in providing a water supply, the utmost limit being about £13.

Dr. Woodford (Berkshire) referred to the difficulties which arose from rural sanitary authorities having no power to regulate the erection of building unless they applied for urban powers, and said though these were generally granted on applicetion they very often came too late to prevent the evil.

Dr. Alfred Carpenter spoke at some length on the necessity for further education, which he thought ought to be relied on more than compulsion. The greatest part of the obstacles which medical officers met with in getting their requirements carried out was ignorance on the part of the people.

Sir Thomas Acland, Bart., M.P., also dwelt on the importance of education, and thought it was very desirable that all officers appointed under sanitary authorities or boards of guardians should possess some certificate of competence to fulfil the duties.

Dr. Alfred Carpenter said the Sanitary Institute of Great Britain quarterly held examinations for surveyors and inspectors of nuisances in order to meet this requirement.

The Chairman said no doubt all agreed pretty well as to what might be called a sanitary house, but the mode of construction must differ according to the circumstances of the case. There was no reason why buildings in flats should not be as healthy as smaller houses if they were properly arranged. The great difficulty was finding the money to build these houses. In the country districts he did not see why proper dwellings should not be provided for the labourers who had to cultivate the farms, in the same way as stables were built for the horses, and even in towns it might be desirable for manufacturers to build houses for their workmen, as had been done at Mulhaus and various parts of the Continent, where the workman got a good house built for him and shared in the year's profits. He believed more powers were required, but still those already existing were not utilized to nearly their full extent. In many cases he thought it would be right that public authorities should erect workmen's dwellings, and that they might be made to yield a fair return. He agreed with what had been said on the importance of education, and he believed the Health Exhibition would, in that point of view, have a very lasting effect on the improvement of the sanitary administration of the country.

(To be continued.)

ROYAL INSTITUTION.

Electric Induction Experiments.

A lecture of some interest on the above subject was delivered by Mr. Willoughby Smith, before the Royal Institution, on Friday, the 6th inst. The results of some experiments were described by the lecturer as seeming at variance with those of similar experiments by Faraday. Mr. Smith commenced by explaining the methods of producing induced currents, and showed that their comparative strength could be easily measured by means of the reflecting galvanometer. One of the first experiments he made was to show the changes effected by the introduction of a plate of copper or iron between the primary and secondary circuits of an induction coil. If the induced current was formed by one hundred reversals per minute, the insertion of an iron plate caused the induced current to decrease by more than one-half, whilst the insertion of a similar copper plate produced no apparent change. If, however, the reversals were increased to the rate of one thousand per minute, the insertion of the iron plate still reduced the current rather more than one-half, but the insertion of the copper plate caused a decrease to about one-fifth. The lecturer then referred to the experiments made by Arago and Faraday upon a revolving disc of copper in an electric field, and stated that he considered from the results he obtained that the revolving disc might consist of iron or any other metal which is a good conductor. He also remarked that although an equal induced current was obtained from a revolving disc of iron at equal distances before and after the disc entered the electric field, yet with a copper disc the induced current was about two and a half times as strong at a certain point of the disc after leaving the electric field as at an equal distance before entering it. The lecturer considered this difference due to the slowness with which the polarization of copper is effected, and stated that this difference is increased in metals of lower conductivity, with the exception of lead.

Parliamentary and Law Proceedings.

The Extraordinary Case of Strychnia Poisoning.

The adjourned inquest on the body of Thomas Cross, aged 72, a road-sweeper, who was supposed to have died from the effects of the administration of strychnia, was resumed by Dr. Danford Thomas, the Coroner for Central Middlesex, on May 30.

It will be remembered that the deceased suffered from chronic bronchitis, and died suddenly after taking a powder, given him by a married daughter named Isabella Todd, who had recently arrived on a visit from Herne Bay.

The jury considered that the attendance of the drug gist from whom the powders were purchased was most desirable.

Mr. W. Neville Wheeler, druggist, of the Hackney Road, said the powders in question were sold by him. They contained nothing but calomel, and it was not possible that a mistake of any kind could have occurred. The poisons were kept apart from the other medicines, and he had not supplied strychnia or nux vomica in any shape or form.

Mr. Augustus Joseph Pepper, Examiner in Forensic Medicine in the University of London, and Surgeon to St. Mary's Hospital, stated that he had received the contents of the stomach for analysis, and had handed them on to Mr. Luff.

Mr. Arthur Pearson Luff, of the Marylebone Road, said that he had made the required analysis, and had detected the presence of strychnia. Neither he nor Mr. Pepper could say how much poison the stomach contained, but it was more than sufficient to kill the deceased.

Mr. Josiah Haynes, who described himself as an auctioneer, said that Mrs. Isabella Todd had formerly lived with him as his housekeeper. She was in the habit of taking calomel powders. He had some strychnia in his possession, which he had purchased to kill a dog, and this he gave to Mrs. Todd by mistake. They had been out together one day; and, at the Victoria Park Station, she not being very well, he took from his pocket what he thought was a calomel powder, telling her to take it at bedtime, as it would do her good.

The Coroner remarked that it was highly dangerous to carry about deadly poisons in one's pocket, and asked how it was that witness had it with him.

Mr. Haynes replied that about four years ago, wishing to kill a dog, he purchased from a friend, a druggist in Somersetshire, some strychnia, some of which he gave to the dog and killed it, whilst the remainder was put away in a box. A few days ago, whilst turning over some papers, he accidentally came across it, and put it in his waistcoat pocket for safety. On reading an account of the case in the papers, he felt in his pocket for the strychnia and found it gone, whilst the calomel powders were still there.

Mrs. Todd, on being recalled, said that Mr. Haynes had at different times given her calomel powders and other medicines, and she remembered his giving her one a fortnight ago, telling her it would do her good.

The Coroner said, if the jury believed the evidence of Haynes, the whole matter was explained as to how Mrs. Todd became possessed of the poison, and there could be no doubt that she divided it into two parts and gave it to her parents.

The Jury returned a verdict to the effect, that death had resulted from strychnia, administered by Isabella Todd in mistake for calomel; and censured the witness Haynes for his "careless and inexcusable conduct" in carrying about poisonous powders.

Death from Chloral.

On Monday, June 9, an inquest was held at Batley, before Mr. Taylor, Coroner, to inquire into the cause of death of Mrs. Mary Hepper. The deceased, who was 67 years old, has for the previous fortnight been at the house of her son-in-law, Mr. C. D. Grundy, dentist, Batley, on a visit. It appeared from the evidence that about eleven years ago the deceased had a fall, which caused a shock to her nervous system, from which she never perfectly recovered. A doctor prescribed for her small doses of chloral to induce sleep, and she had continued the practice of taking this drug ever since, with the exception of a period of two years. It was shown that during her visit to Batley she had taken several doses, although her daughter and son-in-law had tried to prevent her having access to it. She was in bed most of last week, and on Friday night she had a small dose of chloral, after which she continued in a state of slumber until about half-past four o'clock on Saturday afternoon, when she died before a doctor could be got to see her.

The Jury returned a verdict of "Died by misadventure, through taking an overdose of chloral."—*Leeds Mercury.*

Poisoning by a Patent Medicine.

Dr. George Danford Thomas has held an inquest at the University College Hospital, relative to the death of Louisa Hilda, aged twelve months, daughter of a hawker.

Evidence having been given as to the administering of a patent medicine to the infant, the Coroner said there was no doubt whatever that patent medicines were very injurious to children, and should only be given to them under medical advice, for it was well known that they sometimes contained an amount of morphia which would, especially in the case of a child such as the deceased, do more harm than good. The poor saw these patent medicines widely advertised to cure all diseases, but it was to be hoped that before long the law would be altered so that persons would have to make known the contents of each patent medicine before selling it.

The Jury, in returning a verdict in accordance with the medical evidence, expressed their disapproval of patent medicines being given to children without medical advice.—*Standard.*

Obituary.

Notice has been received of the death of the following:—

On the 6th of May, Mr. Richard Lake, Pharmaceutical Chemist, Plymouth. Aged 38 years.

On the 16th of May, Mr. William Adams, Chemist and Druggist, Plymouth. Aged 77 years.

On the 25th of May, Mr. William Pike, Chemist and Druggist, Lower Kennington Lane, London. Aged 58 years.

On the 26th of May, Mr. John Edisbury, Chemist and Druggist, Liverpool. Aged 68 years.

On the 1st of June, Mr. Frederick John Gunn, Chemist and Druggist, late of Axminster. Aged 56 years.

On the 3rd of June, Mr. David Reid, Pharmaceutical Chemist, Aberdeen. Aged 63 years. Mr. Reid had been a Member of the Pharmaceutical Society since 1853.

ANSWERS TO CORRESPONDENTS.

F. Chabot.—Your letter has been handed to the Secretary, who will probably communicate with you on the subject of it.

"*Joules.*"—(1) With pure bromide of sodium and distilled water the phenomenon mentioned has never been observed by us. (2) If the potassium iodide be dissolved in half the water, and the liq. hydrarg. perchlor. be diluted before being mixed, the hydrarg. biniod. formed will be redissolved and the mixture will remain clear.

W. Lyle.—See a paper on "Oleate of Bismuth" in the *Pharmaceutical Journal*, [3], vol. vii., p. 469. There is no recognized formula for an ung. bismuthi oleatis, but a 10 per cent. ointment would be a suitable strength, reducing the oleate either by simple ointment or vaseline.

X. Y. Z.—A pharmaceutical chemist is not exempted as such from filling the office of overseer.

J. H. Beacock.—A reply to your question would involve giving an opinion upon a legal point, for which we have no qualification.

Communications, Letters, etc., have been received from Messrs. Mercier, Wilkes, Fennell, Marshall, White, No. 1.

A NEW GLUCOSIDE FROM STRYCHNOS NUX-VOMICA.

[*First Notice.*]

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy;

AND F. W. SHORT,

Assistant Demonstrator of Practical Chemistry in the School of Pharmacy.

In the course of a complete chemical and botanical investigation of *Strychnos Nux-vomica*, with which we have been occupied for some time past (the results of which will shortly be published), a hitherto unnoticed constituent of the fruit has been discovered, and on further examination proved to be a new glucoside.

The body was first isolated from the pulp in which the seeds lie embedded within the fruit. This pulp has never received a full chemical examination. It was tested for strychnine by Hanbury ('Pharmacographia'), and the presence of this alkaloid definitely shown. In order to fully examine the constituents of nux vomica pulp, it was dried and exhausted with that mixture of chloroform and alcohol (100 : 25) which we have previously shown to be the best and most suitable solvent for extracting the alkaloidal constituents from nux vomica seeds. The exhaustion was effected in the apparatus for hot repercolation and continuous extraction devised by us and described in this Journal (*Pharm. Journ.*, [3], xiii., 633). The chloroform-alcohol percolate as it cooled deposited crystals; these were separated and dissolved in alcohol and the solution spontaneously evaporated. In this way a mass of nearly colourless prismatic crystals was obtained. These crystals fused when strongly heated, then charred, and finally oxidized without leaving any ash; they contained no nitrogen, as was shown by their yielding no sodium cyanide when heated with metallic sodium. A larger quantity of pulp was next exhausted with chloroform and alcohol. The crystals deposited from the solution were thrice recrystallized from ordinary alcohol, and finally again from absolute alcohol. The perfectly colourless prismatic crystals thus obtained were analysed by combustion with lead chromate, when the following results were obtained:—

	Found. I.	Found. II.	Calculated. For $C_{25}H_{34}O_{14}$.	Calculated. For $C_{25}H_{36}O_{14}$.
C	53·38	53·77	53·76	53·57
H	6·61	6·59	6·09	6·43
O	40·01	39·64	40·15	40·00
	100·00	100·00	100·00	100·00

It is seen from these results that the formula of the substance which we propose to call *loganin* (Loganiaceæ) is most probably $C_{25}H_{34}O_{14}$, although this formula will require confirmation in other ways, for these empirical results might also lead to the formula $C_{25}H_{36}O_{14}$. The first formula is that given to the glucoside arbutin (from *Arctostaphylos Uva-ursi* and *Pyrola umbellata*) by Hlasiwetz and Habermann (*Ann. Chem. Pharm.*, clxxvii., 339), although, according to Schiff, the substance analysed by these chemists was a mixture of arbutin ($C_{12}H_{16}O_7$) and methyl arbutin ($C_{13}H_{18}O_7$). Habermann has since (*Monats. f. Chem.*, iv., 753) upheld the correctness of the original formula by further experimental results. But, be this as it may, the glucoside from *Strychnos Nux-vomica* is shown to be radically distinct from both arbutin and methyl arbutin, by a much higher melting point, and by not yielding quinol (hydroquinone) or methyl-quinol when acted on by diluted sulphuric acid.

The crystals of loganin lose no water when slowly heated from 100°—180° C. When further heated they liquefy at 215° C., this observation being made with the substance very gradually heated on the surface of mercury contained in a beaker, supported on a non-conductor in an air-bath—in fact, by a modification of the method for determining melting points originally suggested by Professor Redwood. This melting point was redetermined, using a capillary tube sealed at one end, into which the substance was introduced, the tube being slowly heated in a bath of glycerol (glycerin). It was noticed that the crystals softened at 200° C. and become transparently liquid at 215° C. Loganin is easily soluble in water and alcohol, less soluble in ether, chloroform and benzene. The aqueous solution is not precipitated by any of the alkaloid reagents, neither by lead acetate nor silver nitrate; further the solution is not affected by ferric chloride. Loganin develops no colour when acted upon by nitric acid or other oxidizing agents, although it is powerfully oxidized by a mixture of sulphuric acid and potassium dichromate; bromine water is decolorized by a solution of the glucoside. The most characteristic reaction of the substance is found in its behaviour with concentrated sulphuric acid. A very small quantity of loganin, when gently warmed with a few drops of concentrated sulphuric acid, yields a fine red colour, which, on standing, develops into a deep purple. An aqueous solution of loganin does not reduce Fehling's solution. When boiled with dilute sulphuric acid the glucoside is resolved into a glucose (reducing Fehling's solution) and a body which we propose to call *loganetin*. This substance, like loganin, gives the characteristic reaction with sulphuric acid although the purple colour does not develop so rapidly. Loganetin is soluble in water and alcohol, less soluble in ether and chloroform. The aqueous solution of loganetin is not precipitated by silver nitrate or lead actate, nor coloured by ferric chloride. The substance gives no colour when acted on by nitric acid. We are now engaged in a further study of loganetin.

From the amount of loganin obtained from the pulp on which we worked it appears to exist to the extent of from 4 to 5 per cent. in the dried material.

We now proceeded to examine the seeds of *Strychnos Nux-vomica* for the same glucoside, although its occurrence has never been noticed by other observers, nor does any mention of such a constituent appear in the original analysis of Pelletier and Caventou. About one hundred grains of the finely powdered seeds of *Strychnos Nux-vomica* were exhausted with boiling alcohol. The alcoholic solution was treated with tannin to precipitate alkaloid, and the excess of tannin was removed, together with colouring matter, by evaporating to dryness with lead hydrate. The dry residue was exhausted with absolute alcohol; this when evaporated left a small quantity of residue giving the characteristic purple colour which loganin forms with sulphuric acid. The aqueous solution of the residue did not reduce Fehling's solution until it had been boiled with dilute sulphuric acid. In a second experiment the alcoholic solution of the seeds was evaporated to dryness, extracted with water, and the aqueous solution precipitated by lead oxyacetate. From the filtered liquid the alkaloid was nearly entirely precipitated by tannin. The solution after filtering was evaporated to dryness and extracted with chloroform. When the chloroform was evaporated, a residue was obtained which gave the reaction for loganin with sulphuric acid very distinctly. We have since found that the presence of loganin may be detected with great readiness in the alcoholic extract of nux vomica which is official in the British Pharmacopœia by extracting it with boiling ether, which removes also a little oil with a trace of alkaloid. The residue from the evaporation of the ethereal solution gives the reaction of loganin when gently warmed with sulphuric acid.

It has been shown in this preliminary note that the pulp of the fruit of *Strychnos Nux-vomica* contains to the extent of 4 or 5 per cent. a new glucoside which we have termed loganin, the chemical composition and properties of which have been described. It has also been shown that loganin is contained in small quantity in the seeds of *Strychnos Nux-vomica* and in the pharmaceutical preparations made from them. In the future we hope to be able to indicate the chemical constitution of loganin and loganetin and to discover the relations (if any) of these bodies to the alkaloids strychnine and brucine. The physiological action of loganin will also receive attention. The pulp of *Strychnos Nux-vomica* was collected and prepared for us through the kindness of Dr. W. C. Ondaatje, F.L.S., of Galle, Ceylon, to whose invaluable services in aiding this investigation we shall allude in a forthcoming paper. For this is the least of our obligations to him.

THE ECONOMIC APPLICATIONS OF SEAWEED.*

BY EDWARD C. C. STANFORD, F.C.S.

(*Continued from page* 1012.)

There are two distinct and well defined varieties of kelp:—Cut weed or black-wrack kelp, and drift weed or red ware kelp. Cut weed kelp is the old soda-producing variety, and is made from the three Fuci, *Fucus vesiculosus*, *F. nodosus* and *F. serratus*; these grow on the rocks in the order named, the latter being the most submerged and containing the most iodine, though all contain but little. The plants are cut at low tide, floated ashore, dried and burnt; the weed does not soften much by rain, and it can always be obtained in the fine natural harbours of the West of Scotland and Ireland. This kelp, burnt into a dense fused slag, contained the most carbonate of soda, and was that variety which employed so many poor crofters and cottars, and enriched so many highland lairds. It is now worthless, and the Fuci, which hang from the rocks at low water in luxurious festoons in these lochs, are now entirely unutilized. I have seen 10,000 tons of this weed cut in a single loch, in a few weeks of summer.

The drift kelp is made from two varieties of red weeds, or laminaria, the *L. digitata*, and the *L. stenophylla*, the former known as tangle. Both are always submerged, and are torn up by the violent gales, so common on the west coast; both are sometimes cut in Ireland with long hooks under water from boats. These plants, especially the latter, suffer very much from rain, and are often, after drying, almost valueless; but if well saved, contain ten times as much iodine as the Fuci.

This is the only kelp now used for making iodine, and it ought to be burnt into a loose ash; but although they employ a different material, we have to deal with the same people, and they still insist on raking it into a molten slag, with iron clauts, at great extra trouble, so much so that the men of the family are obliged to do this part of the work, under the erroneous impression that it will weigh heavier, thus mistaking specific gravity for weight; the fact being that they drive off more than half the iodine, and a great deal of the salts, spending several extra laborious hours in reducing the value to a half. It may be asked why we allow it? An incident which occurred to me may answer that question.

Some years ago, when I had to take a large quantity of black wrack kelp in North Uist, it was made to enable the people to pay their rents, and could not then be given up, though it has been since. I tried hard to get some improvement made in the direction of burning the weed at a lower temperature. The people were assembled in great numbers, and the sheriff eloquently harangued them in Gaelic for me. Their objections were threefold: it would not yield so much, it would not be so good and it would take too long. The late Sir John P. Orde, the proprietor, and his factor were present, and it was agreed at last that the most experienced kelper and myself should try the experiment, each to have a certain quantity of weed weighed out to him, and each to burn it his own way. As I expected, my lot was finished first. The yield was 25 per cent. greater, and the product was also, weight for weight, 25 per cent. more valuable. Any one can understand this double advantage of ash *versus* slag. The old man, my opponent, on the result being explained to him, make a remark in Gaelic, which was translated for me as follows:—"I have been making kelp for fifty years and more, and am I to be taught by a young Sassenach with no beard on his face to speak of?" That was the only result of the experiment. How could I explain to him, especially in Gaelic, the difference between specific gravity and weight, to say nothing of quality? As they would not improve the process, the work had to be stopped, and their evidence before the Royal Commission shows how much they have missed it. We took away their clauts, but it was no use; landing once in the middle of the night, I came upon a group hard at work with new irons, raking off the salts, and making themselves hideous, for so intense is the heat, that the soda volatilized gives a strong monochromatic yellow flame which does not improve the beauty of the workers.

To show that this extraordinary idea still prevails, I quote the following from a daily paper, referring to the island of Tyree this year:—

"The men attending the kilns used to turn over the burning mass with iron 'clauts,' but about two years ago the company forbade the use of the 'clauts,' and the kelp is simply reduced to ashes instead of a hard substance. It may be better fitted for manufacture in this state, but it is also evident that it will take more of it to make a ton than by the old process."

It has one advantage for them; being on the sandy shore, or shingle, it enables them to rake in, and embody with the fused kelp a quantity of sand and stones. We sometimes get a block of granite thinly veneered with kelp from our Irish friends, to remind us, I presume, of their national wrongs, and take a slight revenge.

The great heat involves the additional disadvantage that the carbon reduces the sulphates to sulphides, which involve considerable expenditure of oil of vitriol to decompose them, so that sulphur thus deposited is one of the bye-products of the lixiviation of kelp. We are, therefore, compelled to reverse the ordinary process, and manufacture sulphur from sulphuric acid.

The usual yield of kelp from 100 tons of wet seaweed is 5 tons, and as only half of this is soluble, 2½ tons forms the total valuable product of the labour of cutting, carrying, drying, and burning 100 tons of wet seaweed. The burner in many parts, does not receive more

* Read before the Applied Chemistry and Physics Section of the Society of Arts. Reprinted from the Journal.

than £2 per ton, sometimes less, so that all this labour is done for 2*s.* per ton of weed. When it is also remembered that bad weather often reduces this payment to nothing, it is easy to understand that this occupation is soon given up where any other employment can be obtained. Moreover, the weed is dried in a climate where a native comes up to you with the rain pouring off his hat and nose, and outrages your sense of sight by informing you, if he knows "the English," that it is "a wee misty." The large mass of material to be dealt with, the stormy character of the coasts, the constant moisture of the climate, all tend to still further reduce the quantity obtained. Even with favourable conditions the yield is only 5 per cent., which is quite inadequate to afford profit either to the maker or to the lixiviator.

These evils were fully pointed out in my former paper, and a method was then suggested by which several new products could be obtained, and the whole of the iodine secured. I proposed to submit the seaweed to destructive distillation in iron retorts, thus obtaining a loose, porous charcoal, which retains the salts and the iodine; ammonia, acetic acid and tar were obtained from the distillate. In looking over the tables published in my former papers, some of the diagrams of which are once more on the wall, I notice that the amount of iodine lost in kelp was much under-estimated; much too low a figure having been taken for the produce of iodine. The amount of kelp then made was 10,000 tons in this country, and 24,000 in France; and I estimated the loss of iodine, in this country alone, at 50,000 lbs. annually, it really was about three times that amount, or 150,000 lbs., worth, even at the present low price, £37,500, a sum in excess of the whole value of the additional new products proposed to be recovered.

The Duke of Argyll was the first to see the value of the improvement suggested, and the new process was first carried out in his island of Tyree, in 1863, where works were erected for the pnrpose; soon afterwards works were also erected in North Uist, under an arrangement with the late proprietor, Sir John P. Orde; and more recently in Ireland.

In some respects, Tyree was the best place that could have been selected; in others, the worst. The wildness of its shores, and its numerous outlying rocks, make it the deposit of much drift weed. The inaccessibility and the great difficulty of landing heavy machinery, etc., made the erection of works extremely difficult. The factor calculated that 30,000 tons were used annually for manure, and that four times that quantity was lost. Our calculations were based on recovering 16,000 tons of this, and if even that quantity could have been obtained, the works there would have had a very great success, and turned ont more iodine than all the other Highland shores put together. It is impossible, however, to estimate the amount of seaweed thrown up in a storm, and the sea has an awkward habit of calling again, and removing a good deal of it, or covering it over with sand. This seaweed is also much injured by rain, which soon washes out the salts and iodine. It is a nitrogenous substance, and is quickly devoured by maggots, which become flies, and the material, like some other riches, speedily takes to itself wings and flies away, so that when once I carted a large quantity to the works for experiment, some knowing ones observed that the Sassenach had taken a great deal of trouble to put in the material, but it would not give him any kind of pains to put it out, as it would leave him of its own accord. I may add that it did not; there is nothing so offensive as rotten seaweed, but I had preserved the weed with chloride of calcium. In the winter the long sea rods are thrown up, and these when properly stacked bear a good deal of exposure. There was much difficulty in getting the people to collect these at first, for it was a new thing, and they did not believe in it. They soon found out, however, that it affords winter employment for what they call "a lairge sma' family," and which, to do them credit, most of them possess, as children can work at it. It consists simply in stacking the tangle out of reach of the tide. This work has been going on ever since 1863, and none is lost that can be secured. The works in Tyree and in North Uist are still continued, to the great advantage of the people. For the latter the tangle is also collected in South Uist and shipped to Loch Eport. Both these islands also yielded large quantities of black-wrack kelp, which is now entirely given up.

The works were lighted with the gas obtained by distillation, but after the gas has passed through all the purifiers, it still burns with a strong monochromatic yellow flame. The ammonia obtained is all used as manure for the farm; for whatever other business you follow in these outer islands, you must be a farmer, to feed your horses, etc. The tar is used for the roof of the works; and I may state here, that after great experience of large roofs, many of which have been blown away, I prefer a lattice girder low felt root. No one who has not witnessed a winter gale in one of the Hebrides can form an idea of it. We find it advisable to raise the walls two feet above the girders on each side. I would also mention here that there is no building so efficient or suitable for the damp climate of these outer islands as concrete. The shingle of the shore is always there as the bulk of the material, and cement only has to be sent out. A vessel loaded with quick lime, anchored off one of these islands in a gale, is not a happy or a safe possession, and I know from experience that it does not contribute to the sweetness of sleep.

Iron retorts, heated by coal or peat, were at first used, but these were superseded by brick ovens, which are now employed without fuel. The tangle swells in the retort, and produces a charcoal of great porosity, from which the salts are easily washed out, and there are no sulphides. The residual charcoal is a very efficient decolorizer and deodorizer, but has never been largely used for these purposes. I shall mention presently an application of it.

The following analysis shows the comparison of this charcoal with that from bone. It does not in any way approach the composition of that from wood:—

	Seaweed.	Bone.
Carbon	52·54	11·77
Phosphates	10·92	77·70
Calcium carbonate	15·56	8·43
Calcium sulphate	—	·35
Magnesium carbonate	11·34	—
Alkaline salt	5·70	1·09
Silica, etc.	3·94	·66
	100·00	100·00

My experience in the use of peat may be worth recording. I found it give a very fair red heat; we cut and stacked about 600 tons a year of good quality in North Uist, it cost 2*s.* 6*d.* per ton, and I do not think it can be obtained for less. There was no royalty or rent, and the bog was close to the works. It required three times the quantity compared with coal, which greatly increases cost of firing. There is this peculiarity about peat that, where a large supply is required, its cost increases with the quantity collected, because a larger area must be worked.

The winter tangle forms but a small part of the seaweed used for kelp. In the spring and autumn large quantities of Bardarrig or tangle top come ashore, and this is the substance most difficult to deal with. It is ruined for kelp-making by rain, and it will not repay cartage to a long distance. Even washing about in the sea spoils it. To work it by my process would require a large number of small works, which is out of the question, so that it is still mostly made into kelp in the old way, with all its attendant evils. It is this substance which I propose now mainly to deal with. I am convinced that no process will deal effectually with it unless it will afford the means of removing it to central works, say at Glasgow, involving a cost for carriage equal probably to the cost of the weed, doubling in fact its first cost. There are two ways of removing it, either wet or air dry. I prefer the latter, although I have proved that it can be perfectly well kept in a silo, a specimen so kept for several month having reached me perfectly good, and still containing 83·8 per cent. moisture; and it has been also proved that such a covering of earth as that used for potatoes is an available silo. Most of this material can, however, be got air dry, if, as soon as obtained, it is put in a rick and thatched over, a good deal of it being lost at present while they are waiting for enough to burn into kelp, which cannot be made in a small quantity, and for a way they have of putting it in small stacks to get damp again, because they object to burning it too dry. Twenty thousand tons of this dry material could easily be got in Ireland alone. Four hundred thousand tons of the black wrack was the usual annual collection in the Hebrides in former years, now all unutilized, so that there is ample material if use can be found for it. It is a well known fact that the Fuci grow better when regularly cut.

We are not, of course, limited to Ireland and the Highlands, as any demand for the raw material would open up new and very extensive sources of supply.

The difference between kelp-making and distillation in retorts is shown by the following actual experiment on eight tons of tangle. Four tons were burnt with great care into kelp, and four tons were carbonized in a retort with the following results:—

	Cwt.	Per cent.
Kelp produced	15	18·7
Char „	30	37·5
	Salts. Cwt.	Iodine. Lbs.
Produce of char	8·77	29·25
„ kelp	6·57	13·27
Loss in kelp	2·10	15·98
„ per ton of tangle . . .	0·53	4·00

As a rule the kelp does not contain anything like this. The presence of sand, particularly, adds much to the volatility of the iodine.

A rich sample of seaweed ash, exposed in a platinum capsule over an ordinary Bunsen burner for twenty-four hours, will not retain a trace of iodine.

The sand in kelp is either shell sand, which is mostly carbonate of lime, or flint sand, which is silica; both are highly prejudicial, as the following experiment shows—100 grains of a rich seaweed ash was in each case heated for ten hours over an ordinary Bunsen burner.

	Per cent.	Lbs. per ton.
The ash contained of iodine . .	·8930	20
The ash after heating ten hours .	·4911	11
The ash with 50 per cent. limestone	·3572	8
The ash with 50 per cent. sand .	·2235	5

New Process.

The salts made from kelp at present are as follows, taking an average on 20,000 tons:—

	Per ton.
Muriate (95 per cent. potassium chloride)	5 cwt.
Sulphate (75 per cent. potassium sulphate)	1·8 cwt.
Kelp salt (sodium chloride, containing carbonate = 8 per cent. alkali) . .	3·8 cwt.
	10·6

Iodine, 12½ lbs per ton.

I found, in the first instance, that these salts could be easily extracted from the seaweed, by simple maceration in cold water; the amount so removed from air-dry Laminaria is pretty regularly about one-third of the weight, or 33 per cent., of which 20 to 22 per cent. are mineral salts, and the balance consists of dextrine, mannite, and extractive matter, leaving two-thirds of the plant, or 66 per cent., for further treatment, apparently unaltered.

This residue contains a peculiar new substance, to which I have given the name of algin; and the cellulose; the whole plant being thus utilized.

The comparison between the three processes will, therefore, be as follows, on 100 tons of air-dry Laminaria:—

Kelp Process.

Per cent. utilized, 18.

Kelp, 18 tons	Salts, 9 tons. Iodine, 270 lbs.	Residuals— Kelp waste, 18 tons, valueless.

Char Process.

Per cent. utilized, 36.

Char, 36 tons	Salts, 15 tons. Iodine, 600 lbs.	Residuals—Charcoal, 36 tons, tar, and ammonia.

Wet Process.

Per cent. utilized, 70.

Water extract, 33 tons.	Salts, 20 tons. Iodine, 600 lbs.	Residuals — algin 20 tons, cellulose 15 tons, dextrine, etc.

Showing that the last process has the first advantage of taking out more salts and iodine from the weed than any other; and these, even at present prices, are sufficient to recoup all the expense of carriage and working. Moreover, in the two prior processes, the residuals are those of the first product, in the last these are from the weed itself.

The water extract is carbonized, and the salts extracted. I append analyses of these; they differ from the kelp in containing no sulphides, and in containing calcium and magnesium salts.

Air Dry (Laminaria stenophylla).

21 per cent. salts.

	Per cent.
Calcium sulphate	1·93
Potassium sulphate	9·72
Potassium chloride	31·97
Sodium chloride	48·67
Sodium iodide	1·79
Sodium hydrate	0·13
Magnesium chloride	5·74
	99·95

Residual Weed (Laminaria stenophylla).

2·32 per cent. salts.

	Per cent.
Potassium sulphate	35·27
Potassium chloride	6·72
Potassium carbonate	5·00
Sodium carbonate	49·97
Sodium iodide	2·63
	99·49

It will be seen that 90 per cent. of all the salts are thus removed, and much of those that remain are products of decomposition. These salts are obtained by the carbonization of the water extract. This is not necessary, and may not be advisable; the salts can be fished out during evaporation. I append analysis of a 2 cwt. sample so fished:—

	Per cent.
Calcium sulphate	1·18
Potassium sulphate	14·20
Potassium chloride	27·81
Sodium chloride	55·11
Sodium iodide	1·69
	99·99

Iodine 32 lbs. per ton.

Also of the mother-liquor 54° Twad. evaporated—

	Per cent.
Potassium sulphate	16·35
Potassium chloride	17·48
Sodium chloride	54·98
Sodium carbonate	5·13
Sodium iodide	5·27
Water	·70
	99·91

Iodine 100 lbs. per ton.

(*To be continued.*)

THE INFLUENCE OF TECHNICAL INSTRUCTION ON CERTAIN BRANCHES OF CHEMICAL INDUSTRY.

The following notes on certain special industries, viz.: (1), chemical colours; (2), beet sugar; (3), the alkali trade, upon which the influence of technical education is plainly observable, are contained in the recently issued report of the Royal Commission on Technical Instruction.

I.—*Influence of Technical Training on the Chemical Colour Industry of Germany and Switzerland.*

Among the coal-tar colour works visited by the Commissioners, were those erected on the banks of the Rhine, at Basle, by Messrs. Bindschedler and Busch. These works, though far less extensive than those of Messrs. Meister, Lucius, and Brüning, at Höchst, or of the Baden Aniline and Soda Works, at Ludwigshafen, are carried on in a no less scientific spirit, and the general method of working adopted in all these establishments is identical.

The first principle which guides the commercial heads of all the Continental colour works, is the absolute necessity of having highly-trained scientific chemists, not only at the head of the works, but at the head of every department of the works where a special manufacture is being carried on. In this respect this method of working stands in absolute contrast to that too often adopted in chemical works in this country, where the control of the processes is left in the hands of men whose only rule is that of the thumb, and whose only knowledge is that bequeathed to them by their fathers.

On entering the works of Messrs. Bindschedler and Busch, one is struck, in the first place, with the adaptation of means to ends, with the substantially-built, well-lighted, well-ventilated workshops, and above all, with the all-pervading cleanliness and neatness. But it is not of these things that we now desire to speak, but rather of the method by which their business is conducted. In the first place, then, the scientific director (Dr. Bindschedler) is a thoroughly-educated chemist, cognizant of, and able to make use of the discoveries emanating from the various scientific laboratories of the world. Under him are three scientific chemists, to each of whom is entrusted one of the three main departments into which the works are divided. Each of these head chemists, who have in this instance all enjoyed a thorough training in the Zurich Polytechnic, has several assistant chemists placed under him, and all these are gentlemen who have had a theoretical education in either a German University or in a Polytechnic School. An important part of the system has now to be noticed, viz., that directly under these scientific assistants come the common workmen, who have, of course, no knowledge whatever of scientific principles, and who are, in fact, simple machines, acting under the will of a superior intelligence. The many and great advantages of this arrangement are patent to all; and the fact of having men of education and refinement in positions of the kind, renders the foreign manufacturer who adopts this system less liable to annoyance and loss (from sources which we need not more nearly specify) than his English competitor, who works on a different plan.

So much for the *personnel* of the works. Now for the mode in which they carry on their work. To begin at the beginning, we find no less than ten well-equipped, airy, experimental laboratories in these works, perfectly distinct from the workshops where the manufacturing processes are carried on. In these ten laboratories, the chief departmental chemists and their assistants work out their investigations respecting the production of new colouring matters, or the more economic manufacture of old ones. To assist them in their work, a complete scientific library is at hand, containing all the newest researches, for these, as we have said, form the material out of which the colour-chemist builds up his manufacture, and no sooner do the results appear of a perhaps purely scientific research which may possibly yield practical issues, than the works-chemist seizes on them and repeats these experiments, modifying and altering them so as at last to bring them within the charmed circle of financial success.

Thanks to Dr. Bindschedler, we are able to quote a specially representative case, and a clear description of one such case is worth a host of generalities. Through the original investigations of Messrs. Emil and Otto Fischer, the attention of the manufacturer was drawn to the leuco or colourless base obtained by the action of benzaldehyde on dimethylaniline, inasmuch as they stated that the salts of these colourless bases become green on exposure to air. Founded on these observations, an endeavour was made to effect the practical manufacture of a green colouring matter by oxidation of these colourless bodies. In order to attain the desired end, the following investigations had to be made by the chemist and his assistants who were to conduct the operations:—

(1.) A cheap method had to be found for manufacturing benzaldehyde.

(2.) A profitable mode of making the leuco-base had to be worked out.

(3.) The proper oxidizing agents and their best method of application had to be determined.

(4.) The best method of purifying and of crystallizing the green colouring matter had to be discovered.

The laboratory experiments on the above points having proved so far successful as to give prospects of good results, operations on a somewhat larger scale were started, and these yielding a satisfactory issue, the manufacture proper of the colouring matter, now well known as malachite green, on the technical scale was commenced; all the operations being watched by, and constantly being under the control of the chemists. But even now their scientific work is by no means ended. Continuous laboratory experiments go on for the purpose of finding improvements in the mode of manufacture. Thus, for example, the improved yield, both as to quality and quantity, of the benzaldehyde is a matter of investigation. Again, the synthetic production of the pure leuco-base by a more direct process is sought for, so as to get rid of loss in working, and to obtain a yield as close as possible to that pointed out by theory. In the same way improvements in the materials used for oxidation, and in their application, are made, so as to effect the oxidation quantitatively, without the formation of bye-products. Lastly, the action of various solvents is examined, so as to obtain the best form of the crystallized colouring matter. As indicating the value of these improvements made after the colour became a marketable article, it is only necessary to state that the price of the crystallized oxalate has been reduced from £2 to £1 4*s.* per kilo.

The foregoing may serve to give a picture of a really scientifically conducted works, where each step in advance is made systematically, as the result of a well-devised plan of operations. This is, indeed, the only means of progress, and this fact is so well recognized in Germany that each of the much larger colour works at Höchst and Ludwigshafen possesses a staff of from thirty to forty well paid and thoroughly trained chemists to conduct their operations. But we are, of course, far from believing that because the methods adopted in these foreign colour works are scientific and productive of good, those made use of in all English works must therefore be unscientific and bad. Taking the whole applications of chemical science we may, no doubt, with truth say that the English industrial chemists have been at least as successful commercially, and certainly as productive in new and important discoveries, as their Continental rivals. The Germans and Swiss, however, have been and still are distinctly before us, not only in the facilities which they possess of obtaining the highest technical training in their numerous Universities and Polytechnic Schools, but what is even more to the point, before us in the general recognition of the value and importance of such training for the successful prosecution of any branch of applied science.

The following statistics give some idea of the magnitude of the colour works of Messrs. Meister, Lucius and Co., at Höchst, near Frankfort, referred to above, and founded in 1862.

The establishment occupies an area of one hundred and fifty acres, of which twenty are covered with buildings. The staff includes fifty-one scientific chemists, fifty foremen, fifteen managers and engineers, and seventy-seven clerks and commercial men, with fourteen hundred workpeople. The works possesses its own railways, forty-one boilers, with a heating surface of four thousand square yards, and seventy-one motors, either steam, water, or gas-engines. The workmen and officials are domiciled in houses belonging to the company, and restaurants, baths, sick clubs, and pension funds have been established for the good of the employés. There is also a fire-brigade with five hand-engines, and one steam fire-engine. The total supply of water, from one hundred and forty-five fire cocks, amounts to 30,000 cubic feet per hour.

In 1882 the products of these works amounted to:—

(1.) 6,600,000 lbs. weight of alizarine.

(2.) 2,200,000 lbs. weight of aniline oil.

(3.) 1,540,000 lbs. weight of aniline, resorcin, and naphthol.

Colours.

The following are the separate products classed together under the last head:—

Aniline and aniline salts.

Fuchsine (no arsenic acid is used in its preparation).

Methyl violet.

Green and blue colours.

Eosin colours.

Naphthol colours.

Alizarine and artificial indigo.

Quinoline derivative (kairin a new substitute for quinine).

Acids.

The most important raw materials employed in manufacturing the foregoing products are as follows:—

40,000	tons	coal.
3,000	,,	tar products.
2,400	,,	caustic soda.
400	,,	potash salts.
2,900	,,	carbonate of soda.
17,400	,,	sulphuric acid.
10,100	,,	various other acids.
1,500	,,	iron borings and filings.
250	,,	wood spirit and spirits of wine.
1,000	,,	various chemicals.
6,800	,,	common salt.
2,050	,,	carbonate of lime.

The whole of the sulphuric, hydrochloric, and nitric acids used, is made on the works.

From about 70 to 80 per cent. of all the aniline colours manufactured are exported, the remainder used in Germany.

About 90 per cent. of the total make of alizarine is exported chiefly to England, but considerable quantities find their way to America, Russia, France, Holland, Spain, and Italy.

One of the most recent and most interesting additions to the above list of products is a derivative of quinoline, termed kairin, lately discovered by Emil Fischer. This substance, which is now being made at Höchst at the rate of about 22 lbs. daily, has been shown to possess important febrifuge properties, even exceeding quinine in activity, and it is not impossible that this artificial product obtained from coal tar may be the means of supplanting altogether the natural alkaloid. The importance of this discovery, should it serve the above purpose, can of course hardly be overrated, and it will then add another and most striking example to the numerous ones which already exist, of the immense importance to the human race of researches in purely scientific organic chemistry, which, at one time, appeared to have no practical value or possible application. It may, therefore, serve again to point the moral, which cannot be too strongly insisted upon, that it is only by the highest and most elaborate achievements of pure scientific investigation that the greatest practical advantages to mankind can be secured.

II.—Influence of Technical Training on the Beet-sugar Manufacture.

Probably no more striking illustration of the rise of a successful and most important industry depending upon the application of the scientific principles of engineering and chemistry can be found than in the Continental beet-root sugar manufacture. The increase in the consumption of sugar in this country has been very great. In 1843 it amounted to 200,000 tons; this figure was doubled in 1854; in 1874 it reached 850,000 tons, and in 1882 1,000,000 tons of sugar were consumed in the United Kingdom. Of these quantities in 1870, 165,000 tons consisted of beet-root sugar, whilst in 1882 the total was over 400,000 tons, valued at £10,000,000. The whole of this amount is imported from Belgium, France, and Germany, as no beet-root sugar is manufactured in this country.

To show the extent and growth of the Continental industry in a small country, we may cite the case of Belgium, with a population of 5,600,000. In 1846 the area under cultivation for beet-root was only 5421 acres; in 1866 this was increased to 44,480 acres, and in 1882 to 86,490 acres. The quantities of raw beet-sugar manufactured in Belgium were in 1880–81 68,000; in 1881–82 73,000; and in 1883 probably 80,000 tons were manufactured in one hundred and fifty-six works; that is, about one ton of sugar is obtained from one acre of beet-root crop. In France and Germany the area of beet crop and the consequent production of sugar is very much larger. The processes of extraction and purification of sugar from beet are complicated and delicate, requiring both scientific knowledge and capital, as the plant necessary for working up the juice into refined sugar is of a very costly character, and the operations require careful and scientific handling in order to ensure success. The juice contains not only sugar crystallizable and uncrystallizable, but also a considerable quantity of inorganic salts and organic substances other than sugar, and the presence of these latter ingredients prevents a large portion of the sugar from crystallizing, and therefore they require to be removed. This removal of the injurious constituents can only be effected when an exact analysis of the juice and of the sugar has been made, and this must be done at each stage of the operation, so that the mode of working shall be properly regulated, and such an investigation is a somewhat complicated process, needing skilled chemical knowledge. The quantity of sugar which is rendered uncrystallizable by the presence of inorganic salts or ash is about five times the weight of the ash.

In order to obtain the sugar which would otherwise be thus lost, many processes have been adopted, and of these that involving the use of strontia is the most recent. This method was secretly worked for some years in certain works in Germany, but it has now been generally adopted under the patent of Dr. Scheibler, chemist to the Beet-root Sugar Institution. By the use of the strontia process large profits have been made, and the plan has been successfully introduced into France and Belgium. The Continental beet-root sugar manufacture, partly of course in consequence of the Government bounties, has been a very profitable one; annual dividends as high as 100 per cent. having been paid by some sugar-mills. It would seem, however, that owing to the great increase in the number of these establishments, the trade has seen its best days.

The question of the cultivation of suger beet in the United Kingdom, and especially in Ireland, though it has received a certain amount of attention in various quarters, has not come to any practical issue. About 1850, Lord Clarendon, then the Lord Lieutenant of Ireland, ordered an official inquiry on the subject of the growth of beet-root in that country, and the results of that inquiry, presented to Parliament in 1852, showed that 78 per cent. of the beets grown in Ireland were rich enough in sugar to be worked, whilst the corresponding amounts for England and Belgium were 75 and 70 per cent. respectively. At that time the West India sugar had the command of the market; the sugar trade has, however, since that date been revolutionized, but no step has yet been taken by agriculturists and capitalists to commence the growth of sugar beet and the manufacture of beet sugar in this country. To produce the 400,000 tons of beet sugar now imported from the Continent we should need as many acres, but as the beet crop is taken only every three years the total acreage required would be 1,200,000. A large proportion of this, if not the whole of it, could be found in Ireland, and there can be no doubt that the introduction of such an industry would do much to improve the general agriculture of that country.*

[For further information on the Belgian Beet Sugar Industry, see paper by M. Melin, of Wanze, read before the Liége meeting of the Institution of Mechanical Engineers, 1883.]

III.—Influence of Technical Training on the Alkali Manufacture.

The beneficial action of high scientific and technical training upon the chemical colour and beet sugar industries having thus been shown, it becomes of interest to examine the effects of such education on another no less important branch of chemical manufacture, viz., the alkali trade, and in this instance the comparison of the relative position of the Continental and English works is by no means all in favour of the former. In the first place, as regards the workmen themselves, it may be truly said that in no country does any real amount of scientific education reach the ordinary workmen in alkali works, who are rather labourers than artizans. Moreover, the foremen, both in this country and abroad, are almost invariably men who enter the works either as laboratory boys or as ordinary workmen, and who have risen by virtue of industry and native intelligence, but who have had no scientific training beyond that afforded by the occupation in which they have been engaged. So far, therefore, as the education of the workmen employed in alkali works is concerned, the foreigner has no advantage over us, nor have we any over the foreigner. In the case of the managers and proprietors the matter is, of course, different. On the Continent nearly every manager of a soda works is a man of a very high degree of scientific attainment,—a highly trained engineer, and a highly trained chemist. An English manager, one at least of the older school, on the other hand, is scarcely ever a man who has had a similar training to that of Continental managers before they enter upon the duties of management. The Continental alkali makers are men of wider knowledge and of more extended scientific attainments than their English brethren. Thus, whilst probably none of our English alkali makers could discuss the chemistry of the latest organic colouring matter, nearly all the Continental masters are able to do so. But in the opinion of those best qualified to judge, and speaking of course of the managers of the first class works in each case, there is no doubt that the English alkali makers are just as well acquainted with the scientific bearings and relations of their own manufacture as their Continental rivals. Nor is the foreigner a better alkali maker than the Englishman, for even in cases in which the former obtains better results than are usual in this country, as regards economy of fuel and raw material, the cause is to be sought rather in the fact that his cheaper labour permits him, and his dearer fuel and raw materlal compels him, to do what dear labour and cheap fuel and material absolutely forbid to the English alkali maker, than in any superiority in scientific training of the one over the other. It certainly cannot be said that the English soda industry suffers in comparison with that of the Continent, owing to the want of scientific knowledge on the part of those who conduct it. Men of the highest talent and most eminent for their scientific knowledge are found in all our large alkali works, and it is a remarkable fact that with one or two exceptions, everything in the way of important improvements in the alkali manufacture by the Leblanc process has originated in England. Hydrochloric acid condensing towers, revolving black-ash furnaces, Glover-towers, mechanical calcining furnaces, mechanical salt-cake furnaces, plus-press furnaces, and last but not least, the Weldon plant; each one of these English improvements marks an era in the alkali manufacture, and has been at once adopted as a necessity by all manufacturers. Even the well-known ammonia-soda process, first successfully worked in Belgium, is chemically an English invention (Dyer and Hemming), though made industrial by a Belgian (Solvay). No less remarkable is it that, certainly often in England, and in some cases abroad, those men who have made the most important improvements or discoveries in the alkali manufacture have been self-taught, proving the truth of the axiom that a scientific education cannot stand in place of natural sagacity and workshop training.

It is the opinion of those intimately acquainted with the present condition and future prospects of the alkali trade, both at home and abroad, that such differences as exist between the results obtained on the Continent and at home, are due to differences of national character and local circumstances rather than to a superiority of scientific education, and it may be questioned whether many Continental alkali works could survive in face of English competition, if the import duties by which they are at present protected were abolished.

FAILURE OF THE CINCHONA CULTIVATION IN ST. HELENA.

Following closely upon the unfavourable report upon cinchona cultivation in Ceylon, to which we referred last week, a report has been received from Mr. D. Morris, Director of Public Gardens and Plantations, Jamaica, on the Present Position and Prospects of the Agricultural Resources of the Island of St. Helena, which records the practical collapse of the cinchona acclimatization experiment in that island. Mr. Morris gives the following

* The sugar factory of Mr. Duncan, established some years ago at Lavenham, and which was not successful, is about to be reopened. The use of strontia and other improvements in the manufacture, together with lower railway charges on the roots, encourage the new proprietors to anticipate better results.

detailed account of the various attempts and their results:—

"The proposal to introduce the cultivation of cinchona into St. Helena appears to have been made, in the first instance, by the late Dr. Roxburgh, who, as far back as 1814, recommended that seeds of *Cinchona officinalis* be obtained from South America, and that after plants had been established at St. Helena they should be transmitted to India.

"Sir Joseph Hooker, having on two occasions, namely, in 1839 and 1843, had favourable opportunities of forming an opinion respecting the resources and climate of St. Helena, when Sir Charles Elliott in 1864 began to develop planting operations in the island by the introduction of new and valuable plants, it occurred to him that cinchona, if properly tried, was likely to lay the foundations of a remunerative and successful industry.

"To undertake experiments a skilled gardener, Mr. J. H. Chalmers, was sent out from Kew in 1869, who, having been supplied with seeds, succeeded within a short period in raising several thousand cinchona plants in nurseries at Plantation House. Soon after a nursery was established at Newfoundland (altitude 2400 feet), in the immediate neighbourhood of the highest peaks and of the only uncleared natural forest remaining in the island.

"Mr. Chalmers succeeded altogether in raising about ten thousand plants from seed; and of these possibly more than one-half were planted out either on the slope above Newfoundland and under Actæon's Peak; or, on the Peak itself.

"This portion of the island, it may be explained, lies along the inclines of the central ridge of which Actæon's Peak, Diana's Peak, and Cuckold's Pit Peak form the culminating points. The general elevation is between 2500 and 2700 feet; the mean annual temperature rather below 60° Fah.; and the soil composed of a rich black vegetable mould—peat—overlying marl or decomposed volcanic rock. At this elevation the ridge is bathed in moisture for at least three days of every week; and thus favoured, as pointed out by Sir Charles Elliott, it has become covered with a luxuriant growth of ferns and other plants usually found in the home of cinchonas in South America.

"The prospect for cinchona at first was full of promise; and indeed if the cultivation had been attempted at an earlier period when there was a larger area of indigenous forest to select from, and when plantations might have been established on the northern and more sheltered slopes of the central range the results might have been very different.

"As it was, the plants put out on the terraces at the foot of Actæon's Peak began to die off, and, driven to a last resource, the cultivation was ultimately confined to the narrow ridges of Actæon's and Diana's Peak, which, in many places, are only a few feet wide and fully exposed to the strong trade winds which usually blow in St. Helena for about nine or ten months in the year. Here the soil on the surface was of a promising character, being composed of rich vegetable humus formed by the decayed leaves and stems of tree-ferns and native plants. Below, however, there was nothing but a cold, wet, indurated or slightly friable marl, very unsuitable for the growth of cinchonas, and which in Ceylon and India is known by experience to develop rot or canker in the roots, and to destroy every plant in contact with it. In his last report on the subject, dated December 12, 1871, Mr. Chalmers rightly attributes the large percentage of losses amongst his plants to the superficial nature of the soil, and reports that 'they invariably died soonest in shallow ground, and, on the contrary, lived longest where the soil was of greatest depth.' Further, he remarks, 'there is nothing, either in the climate or situation, of an unsuitable character; the soil alone seems to be at fault, being insufficient for the further development of the plants.'

"Out of about five thousand plants put out by Mr. Chalmers between January, 1869, and November, 1871, at the latter date there were only five hundred and forty of all ages then remaining. These were as follows:—

Cinchona succirubra,	over 2 feet	221
"	" 6 "	84
Cinchona officinalis	" 2 "	81
"	" 6 "	3
Number of both kinds under 2 feet. . .		151
Total . . .		540

"Further experimental trial was stopped by the reduction of the establishments effected by the late Admiral Patey, and Mr. Chalmers left the island.

"From 1872 up to the date of my visit the cinchona trees still living had received some attention, but practically their cultivation was abandoned.

"I went up to the central ridge with the Governor and Colonel Phillips, R.E., on July 31, and spent the day examining the soil and noticing the condition and state of the cinchona trees still remaining.

"Of the trees planted by Mr. Chalmers there were forty fine trees of *C. officinalis*, from 8 to 20 feet high; of *C. succirubra* there were one hundred and sixteen trees, from 8 to 20 feet high. The largest tree of all was a red-bark tree, *C. succirubra*, which measured 18 inches in circumference at 1 foot from the base. Except a few trees in exceptionally sheltered spots, they were all much damaged by wind, and presented a stunted and half-starved condition.

"The ridge on which they were growing formed a portion of the rim of the old volcanic crater of Sandy Bay. On the southern side there was a steep, almost perpendicular, wall of rock, about 100 to 250 feet deep, reaching down to broken lands and ravines clothed with ferns, briars, and the low, bushy growths of cabbage trees, jelico, wild olive and lobelia. On the northern and western sides the slopes, in places, were somewhat easier, but in no place was the ridge more than about 20 feet or 30 feet across. In many places, indeed, it was so narrow that it appeared like an old castle wall, clothed with vegetation.

"The length of the ridge on which cinchona had been attempted was altogether under ¼ mile in a direct line.

"Under the most favourable circumstances it was not possible to place more than about 5 or 7 acres under cultivation in cinchona; but in view of the very unsuitable nature of the subsoil and the large mortality which had taken place amongst the young plants, it is very undesirable to attempt any further experiments. According to the statement of a very intelligent native gardener, trained by Mr. Chalmers, who has been employed since at Plantation House and is occasionally looking after the cinchona plants on the ridge, more than 90 per cent. of the plants put out were lost owing to the unsuitable nature of the soil.

"I visited the ridge again on August 1, and spent the day in exploring the lands in the immediate neighbourhood of the peaks, with the view of finding land offering better facilities for cinchona planting than the ridge itself. In this I was disappointed. Except on the crest of the ridge there is no vegetable deposit or surface soil likely to grow cinchona, the soil elsewhere being very shallow and immediately overlying rock or cold impervious clay.

"Summing up the results of my inquiry, I am of opinion that, while the first impressions were favourable to the possibility of growing cinchona on the highest peaks in St. Helena, the character of the subsoil, together with the exposed position of the locality, would entirely preclude the undertaking being commercially a success; and on other grounds it would be very undesirable to cut down any more of the indigenous forest, which already is reduced to such a small extent."

The Pharmaceutical Journal.

SATURDAY, JUNE 21, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelop s indorsed "Pharm. Journ."*

HAY FEVER.

About this time of the year many persons suffer severe inconvenience from a complaint which does not appear to have been recognized by the medical faculty as a definite form of disease until the earlier years of the present century. It has been defined as a peculiar affection of the mucous membrane of the nose, eyes and air passages, giving rise to catarrh and asthma, and is referred to generally under the name of "hay fever," though it is also variously termed "hay asthma," "pollen catarrh," "summer catarrh" and "rose catarrh." Whether the silence of the older medical writers upon the subject is to be attributed to the disease having been confounded with others that it resembled more or less closely, or whether it is a penalty attendant upon an advance in civilization, and marks an evolutional increase in the sensitiveness of the olfactory organ since the time when the patriarch failed to discriminate between the odour of the skin of the kid of a goat and the smell of a field, is not altogether clear; at any rate the first detailed account of hay fever was not published until the year 1819, whilst perhaps the most interesting contribution to the literature of the subject was made only a short time since by Dr. Morell Mackenzie, in a lecture delivered at the London Hospital Medical College, and published in the *British Medical Journal.** Few, however, as have been the years during which the etiology of the disease has been systematically studied the theories as to its determining cause have been many. Effluvia from grass or hay, heat, and especially the first heat of summer, the continuous action of light, dust, excess of ozone in the atmosphere, the influence of benzoic acid, coumarin and other volatile compounds, have all been put forward as causes with more or less plausibility; but most of them have been put out of court by known facts. For instance, in the United States hay fever is much more common in autumn than during the almost tropical summer; it does not occur at sea in the most sultry latitudes, whilst it is hardly known in the "land of the midnight sun," where the light lasts during the longest periods continuously; neither is it produced by the inhalation of air highly impregnated with ozone. In the opinion of Dr. Mackenzie, however, it has been clearly demonstrated by the experiments of Mr. Blackley, of Manchester, that the cause of hay fever is the action of plant pollen on the mucous membrane.

In the experiments made by Mr. Blackley, upon himself and others, he found that the inhalation of air containing pollen always produced the characteristic symptoms of hay fever, and that there was a direct relation between the intensity of the symptoms and the amount of pollen suspended in the air inhaled. This result is quite consistent with the common belief that the affection is produced by emanations from plants, although the bad name given to the sweet-scented vernal grass (*Anthoxanthum odoratum*) and the holy grass (*Hierochloe borealis*) seems to be based principally upon their more demonstrative fragrant odour, since there is no reason to suppose that their pollen is more active than that of the fox-tail grass (*Alopecurus pratensis*) or those of various species of *Poa* and *Lolium*. The pollen of rye is still more potent, and those of wheat, oats and barley are also very active. Indeed, the chief culprits, in this country at least, seem to be members of the grass family, and careful observations made by Mr. Blackley led him to the conclusion that 95 per cent. of the pollen occurring suspended in the atmosphere in England during the prevalence of hay fever is derived from the Gramineæ. Plants of this order come into blossom between the end of May and the latter part of July, which is precisely the period of the year when hay fever prevails. In America, however, the pollen of a Composite plant, the Roman wormwood (*Ambrosia artemisifolia*) is thought to be the most common cause of the disease. This plant blossoms in August and September, which is precisely the time that hay fever is most prevalent in North America. Besides the exciting causes of this disorder, however, Dr. Mackenzie recognizes the existence of a predisposing idiosyncrasy in certain persons, and among the circumstances supposed to influence this idiosyncrasy, race, temperament, occupation, education, mode of life, sex, heredity and age are enumerated. The influence of race appears in the fact that almost the only sufferers from hay fever are English and Americans, for natives of other countries resident where the disease prevails are rarely affected, it being never met with among Germans or French in New York, in which city it is comparatively common at certain seasons. On the other hand, in Asia and Africa only the English suffer from it. The nervous temperament appears to be a predisposing cause, whilst it is most singular that the complaint is almost exclusively confined to persons of some education and generally to those of fair social position. The rustic is much less subject to it than the citizen, and a larger proportion of men suffer from it than women. The idiosyncrasy is also undoubtedly

* The lecture has been reprinted in the form of a shilling pamphlet, which is published by Messrs. Churchill.

hereditary and becomes manifest in the majority of cases before the age of forty.

It is admitted that at present the treatment of hay fever is unsatisfactory, and that it is better for persons subject to it to keep themselves out of the way of possible excitants than to rely upon obtaining relief by the use of drugs or otherwise when the complaint has once been set up. When, however, it is necessary for such persons to remain exposed to the perils of a pollen-infested neighbourhood, the plugging of the nostrils with cotton-wool, the protection of the eyes by specially constructed spectacles, or the wearing of a gauze bag drawn over the head, somewhat after the *mode* of the veiled prophet introduced to the English-reading public by THOMAS MOORE, are among the protective artifices recommended. As has been mentioned, persons who suffer from hay fever are most commonly of nervous temperament: nerve tonics and other constitutional remedies, such as quinine, arsenic, opium and belladonna, have therefore been employed to ward off or to control attacks. Dr. MACKENZIE states that he has found pills containing one grain of valerianate of zinc and two grains of compound asafœtida pill more useful than any other remedy, the pills being ordered to be taken as the hay season approaches. When the disease is established, tincture of opium in doses of five to seven drops twice daily, and a saline purgative, have been found useful in reducing the secretion, diminishing the sneezing and bracing up the system. The diet should be at the same time nutritious and easily digestible. Dr. MACKENZIE trusts very little to local applications for the relief of the complaint, since many of those recommended appear to be apt to intensify the disease, especially those of quinine and salicylic acid, the recommendations of which appear to have been based upon the assumption that the complaint is due to bacterial agency. He says, however, that when there is profuse secretion with an excessive tendency to sneeze the inhalation of strong ammonia salts often gives great relief, while a soothing effect sometimes follows the inhalation of a "vapour" prepared from compound tincture of benzoin or the insufflation several times a day of a powder containing one-sixteenth of a grain of morphia and one grain of bismuth. For the relief of the irritation of the eyes a lotion containing two grains of acetate of lead and two drops of acetic acid to an ounce of water has been found useful, or a sedative collyrium containing acetate of morphia may be dropped into the eye. The symptomatic phenomena of hay fever are fairly characteristic, and the points in which they differ from those of common catarrh on the one hand or spasmodic asthma on the other have now been clearly made out. For a description of them the reader cannot do better than turn to the lecture that has been the occasion of this notice. It must suffice here to say that hay fever usually comes on very suddenly, varies considerably in its intensity and duration, apparently in direct proportion to the abundance of the *materies morbi*, is marked by a characteristic œdematous puffiness of the eyes, and as a rule first attacks its victims in the daytime and in the summer.

The Registrar has received from the Privy Council Office a copy of an Order in Council of the 11th inst., confirming the appointment of Mr. W. H. Symons as a member of the Board of Examiners for England and Wales.

* * *

We have been favoured by Dr. Murrell with a copy of the programme of the arrangements, so far as completed up to the present time, for the business of the new Section of Pharmacology and Therapeutics of the British Medical Association, at the meeting to commence in Belfast, on the 29th of July. From this we learn that the President of the Section, Dr. Thomas John Maclagan, of London, proposes to move, at the conclusion of his Introductory Address, a series of resolutions relating to the "British Pharmacopœia" and the "Patent Medicines Stamp Act," which will be supported by the Vice-Presidents, Dr. Matthew Hay, of Aberdeen, Dr. Walter Smith, of Dublin, and Dr. William Whitla, of Belfast. An expression of medical opinion upon these two subjects, such as may be expected in the subsequent discussion, can hardly fail to be of considerable interest at the present juncture, especially as it may be supplemented by that of pharmaceutical chemists, several of whom have been invited to attend the meetings of the section and take part in the debates. Amongst the other business that is to be brought forward, there is to be a debate on Antipyretics, to be opened by Dr. Alexander Collie and Professor Quinlan; Dr. Dujardin-Beaumetz, Dr. Thursfield, Dr. Boys and Dr. Currie are to read papers on New Antipyretics; there is also to be the special debate on Indian Drugs, to which we referred last week; and Dr. Shoemaker, of Philadelphia, is to give an explanation of the *modus operandi* of the New Oleates which have been associated with his name.

* * *

The Bill to regulate the practice of pharmacy in France appears to share the experience of the attempts to legislate for medicine and pharmacy in this country. The Bill has been included among the orders of the day since the last week in May, without making progress, and a day or two since it was still as low down as No. 34.

* * *

A short Bill to extend the operation of the Factory Acts to shops, which has just been introduced into the House of Commons by Sir John Lubbock, contains some provisions that might prove very inconvenient if allowed to pass into law without modification. One of them would make it illegal to employ "a young person," *i.e.*, a person under eighteen years of age, during more than twelve hours or later than eight o'clock in the evening of any working day of the week, except one, the limit of which is fixed at ten, whilst on one day the working hours are not to exceed seven and not to terminate later than five in the evening. Another provision would make it illegal to employ "a young person" in a shop at all on Sunday. It is evident that both these provisions would clash very much with the arrangements under which, at present, the public is, in many places, supplied with necessary medicines.

At the last meeting of the Board of Pharmacy of the city of New York a report was presented stating that there were then 2019 registered pharmacists in the city, 860 of whom were proprietors of pharmacies and 1159 assistants. During the three years in which the Board had held office it had examined 107 candidates, of whom 63 failed to pass. There had also been about three hundred prosecutions for the offence of dispensing drugs without a certificate.

* * *

The experiment of raising a supply of medicinal plants in the Government Botanical Gardens in Ceylon appears to have met a fair amount of success. At Hakgala jalap plants have grown most vigorously, and although at the time of the report very few tubers had been found, the bed was full of underground stems by which the plant could be propagated. The few tubers had, moreover, grown to a large size, one that was taken up weighing sixteen ounces. As, however, in the Nilghiris the best results are obtained at an elevation of 7000 feet, whereas at Hakgala the elevation is only 5400, it is thought probable that this may be the explanation of the tendency of the plants to make more leaf and less tuber at the latter place. Tinnevelly senna (*Cassia angustifolia*, var., Vahl) has succeeded perfectly at Anuradhapura, from whence good samples of the drug were sent to the Agri-Horticultural Show in Colombo in August last. Seeds of Mecca senna (*C. acutifolia*, Vahl) have also done well. Beds of seedlings of *Rheum palmatum* and *R. officinale* have been made at Hakgala, but though the crowns look plump and healthy, the plants make little growth. Still as the common garden rhubarb does well, it is thought that the medicinal plants may succeed if kept going until somewhat acclimatized. At Hakgala, too, the chamomile has become thoroughly established and can be increased to any extent. Taraxacum has not, however, done quite so well, the soil being too poor, and the plants having been eaten down by elk. A considerable quantity of fair-sized roots were, however, available for the use of the Medical Department.

* * *

Mr. Bowen, who for the last five years has presided over the Pharmaceutical Society of Victoria, having declined to accept the position for a fresh term, the Council of the Society, at its meeting in April, elected Mr. Huntsman as President. The new Vice-President is Mr. E. G. Hooper, whilst Mr. Gamble and Mr. Shillinglaw have been unanimously re-elected Treasurer and Honorary Secretary respectively. It was reported that twenty-eight students were attending the College of Pharmacy.

* * *

Notwithstanding the declining value of the cochineal crop in Teneriffe, to which we recently referred, it appears from a recent report by Brigade-Surgeon Bidie, that the Indian Government has decided to obtain a supply of cochineal insects from Algeria, with a view to introducing their rearing as an industry into Madras. The fodder and resting plant for the insects to be experimented with is the local prickly pear (*Opuntia Dillenii*), on which, according to Roxburgh, they thrive and multiply.

* * *

According to a recent return there were in the Dutch Government plantations and nurseries in Java, at the end of last year, 3,299,500 cinchona trees, showing a slight decrease as compared with the previous year; in respect to the "Ledgeriana" plants however, there had been a considerable increase. The surplus seed from the Government plantations is now sold by auction at Bandong, and in consequence of the increasing cultivation of the cinchona by private enterprise in Java it has been in considerable demand. At the first auction as much as 20 fl. per gram was paid for some lots of seed from the original "Ledger" trees.

* * *

Referring to the subject of the leaves of a plant, mentioned on p. 976, as being smoked by the natives of Angola, we are informed by Mr. J. R. Jackson, the Curator of the Museum of the Royal Gardens, Kew, that the hemp (*Cannabis sativa*, L.), is no doubt the plant meant, as it is well known on the west coast of Africa under the name "liamber,"

* * *

M. Jamin has been elected to succeed the late M. Dumas as Perpetual Secretary to the French Academy of Sciences by thirty-nine votes against twelve votes given to the other candidate, M. Vulpian.

* * *

It has been announced that a new 'Flora of Oxfordshire' is being prepared by Mr. G. Claridge Druce, which is to be not only a catalogue, but a history of Oxfordshire plants and of the botanists connected with the University and County. Mr. Druce, who is a pharmaceutical chemist, residing in Oxford, and whose name will be familiar to many of our readers, has been promised access to manuscripts and herbaria in the possession of private individuals as well as the active assistance of many eminent botanists; but we doubt not that he will be glad also to receive from fellow pharmacists any information on the subject they may be able to place at his disposal.

* * *

A note in the *Répertoire de Pharmacie* mentions the occurrence of a quantity of tartrate of ammonium (probably the acid tartrate) in a sample of codeine. The tartrate resembled the codeine in its external appearance; it was crystallized in hard rhomboidal prisms, slightly soluble in cold water, but dissolving readily in boiling water, yielding a solution with an acid reaction. The salt is insoluble in alcohol, which property first led to the detection of the admixture and facilitated its separation from the codeine.

* * *

According to the *Pharmaceutical Record* the New York Board of Fire Commissioners has been compelling retail druggists to pay a licence tax of two dollars for keeping "ether, nitrate of silver, and a few other combustibles and explosives." The imposition has, however, been resisted by one druggist, who has obtained a legal decision in his favour, but against this the Board has appealed to a higher court.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, June 26, at 8 p.m., when a "Further Report on the Purification of Crude Antimony Sulphide" will be made by Mr. A. J. G. Lowe. A Report on Physics will be made by Mr. H. Allen, B.Sc., and a "Note on Eykman's Process for the Estimation of Ethyl Nitrite," will be read by Mr. T. S. Dymond.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 18, 1884.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Symons, Tanner, Taylor and Thresh.

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Blain, Alfred Lucas .... Bolton.
Burnett, Joseph Fearon .... Hyde.
Prothero, George Rees .... Pontypridd.
Steward, Josiah William .... Bridgnorth.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Seventeen* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Astley, Frederick Aspinall...... St. Anne's-on-Sea.
Barker, George...................... Mirfield.
Britton, William Brannam...... Barnstaple.
Bunn, James Early Smee ...... Halstead.
Cullinan, Edward.................... London.
Davies, Charles Gardiner ...... London.
Earle, Ernest Haworth .... Hull.
Evans, John Richard .... Dowlais.

June 19, 1884.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Corder, Ekin, Fletcher, Gale, Linford, Plowman, Southall, Symons, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-nine candidates were examined. *Twenty-one* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Burnby, John James .... Bardney.
Heron, Frederick Chambers ... London.
Johnston, William .... Montrose.
Jones, Llewellyn J. W. .... Swansea.
Saul, John Edward .... Rock Ferry.
Sloan, William Guley .... Barking.
Stevenson, George .... Hucknall Torkard.
Watson, Arthur John .... Great Bridge.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Bridgwood, Walter Stuart ...... Birmingham.
Jefferson, John...................... Carlisle.

Certificates of the University of Cambridge.

Poole, Jeffrey .... Birmingham.
Riches, Frank Fraser .... Torquay.

Certificate of the University of Oxford.

Kingzett, John Frank .... Weston-sub-Edge.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly stated meeting of the Council was held on Wednesday, June 4.

Present—Mr. James E. Brunker, M.A., President, in the chair; Messrs. W. N. Allen, Thomas Collins, M.R.C.S.E., Alexander E. Doran, John Evans, L.A.H., William Hayes, E. M. Hodgson (Treasurer), Robert Montgomery, L.A.H., M.R.C.S.E., Robert Simpson, and Aquilla Smith, M.D.

The Registrar read letters from Sir W. V. Harcourt, Home Secretary, and Sir R. H. Collins, thanking the Council for its vote of condolence with the Queen and the Duchess of Albany in their bereavement, which were ordered to be inserted on the minutes.

The Registrar read a communication from the Pharmaceutical Society of Great Britain, stating that after consideration of the circumstances mentioned in Mr. Fennell's letter of February 20, the Society had resolved to accept the offer contained in that letter, and would supply copies of the *Pharmaceutical Journal* to the members of the Society for an annual payment of £20.

The President said this arrangement was on the understanding that the number of members would not exceed about sixty. The Pharmaceutical Society of Great Britain had acted very liberally in this matter.

Mr. Hodgson (Treasnrer) moved—

"That the thanks of this Society be given to the Pharmaceutical Society of Great Britain for supplying the *Pharmaceutical Journal* to our members on the liberal terms mentioned in their letter of April 5, read this day."

Seconded by Mr. Doran and agreed to.

The Registrar read a letter from Mr. G. O. Trevelyan, Chief Secretary for Ireland, acknowledging the receipt of the statement sent by the Council of their views relative to the amendments sought for to the Pharmacy and Poisons Acts.

The President said letters had also been received from other members of Parliament, acknowledging the receipt of the statement sent by the Council. Among them were Messrs. Gibson, M.P., and Plunkett, M.P., both of whom promised to attend to the matter whenever the Bill came before the House of Commons.

A letter was read from Mr. William H. Greer, Belfast, stating that he purposed shortly to present himself for the Society's Final examination, and asking the Council to accept a certificate from Dr. Frankland of his having attended a course of instruction in practical chemistry at South Kensington, although not one of the institutions mentioned in the Society's regulations.

The Registrar was directed to inform Mr. Greer that the Society had no power to accept the certificate of South Kensington without the authority of the Privy Council, but that application would be made to obtain such authority as soon as possible.

The Registrar read a communication from Mr. J. P. Middleton, of Hardwick Street, Dublin, re-submitting a certificate for practical pharmacy given him by Mr. G. H. Grindley, for acceptance by the Council.

After some discussion as to the bearing of the Attorney-General's opinion on the case, and the reply recently given to Mr. Hardy, Dr. Montgomery said as there was some doubt about the case, and as it was stated that other gentlemen who had served their time in the same establishment had had their certificates accepted, he would propose that Mr. Middleton's certificate be accepted. Mr. Middleton had served his five years in the full expectation that he would be allowed to come in for his examination.

The motion was seconded by Mr. Evans and agreed to.

The Registrar read a letter from Mr. W. C. Spencer, of Cork, inquiring whether a pharmaceutical chemist could start a business in conjunction with a registered dentist not qualified as a chemist, and place over their door "E. and S., Chemists and Dentists."

It was resolved that the Registrar be instructed to reply to the letter, informing the writer that such a firm, consisting partly of persons not qualified, could not legally compound prescriptions.

Mr. Allen brought up the report of the Committee on the Visitation of Examinations.

The report contained several recommendations with reference to the conduct of the examinations for the licence, which were adopted.

The principal change recommended was the extension of the examination to three days, so as to give each examiner a day to himself.

The reports of the Examiners for the April Examinations were presented.

The following gentlemen passed the examination for the licence in April last:—

William James Baxter ....Coleraine.
Morgan M. J. D'Arcy............Kingstown.
John Wilson Dickson ....Ballymena.
William Alexander Frizell......Derry.
William H. Griffin ....Ranelagh.
William James Smyth ....Belfast.

Two were rejected. Out of four who presented themselves for the Preliminary Examination, three passed.

The Council then adjourned.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

Assistants' Association.

A general meeting was held in the Society's rooms, on May 28, for the purpose of terminating the session and arranging business for the ensuing one. The President (Mr. N. S. Smith), in congratulating the members upon their position, spoke of the necessity there had been for such an Association in Sheffield, the satisfactory state it was now in, and the fair prospect it had before it. He said that remembering the ready response which various applications of theirs had received, he looked forward to increased educational facilities for the next session, and felt certain if each member would steadfastly bear in mind the real objects of the Association it would have a long and prosperous career.

The Honorary Secretary, Mr. J. Marshall, read the report, showing the Association to be, in all points, in a healthy and flourishing condition.

The President and Secretary were unanimously re-elected, who, with a Committee, consisting of Messrs. Eberlin, Grierson and Humphrey, will manage the business of the Association in the ensuing session.

Proceedings of Scientific Societies.

ROYAL INSTITUTION.

Liquefied Gases.

The last of the Friday evening lectures at this Institution for the session 1884 was delivered on the 13th inst., by Professor Dewar, upon "Liquefied Gases," and proved especially interesting, as during the lecture experiments were made in which the lowest temperature that has probably been obtained in any lecture-room—about $-140°$ C.—was registered. Professor Dewar made an opening statement to the effect that he considered the liquefaction of gases had been one of the most useful aids to the advance of chemistry. He then explained the method by which Faraday effected the liquefaction of gases by heating them in closed tubes, and showed the formation of liquid chlorine by means of a projection upon the screen. He stated, however, that only a few gases could be liquefied by this method, and that the use of liquid carbonic acid as a refrigerating agent had superseded it. He reminded his audience that when this liquid was suddenly released from the pressure under which it had to be kept the fall of temperature consequent upon the vaporization of a portion of it caused the solidification of the remainder, which appeared in the form of a white snow that could be handled with impunity. If this snow were submitted to pressure a solid having the appearance of ice was produced, which unlike the snow sinks in water and emits dense white fumes; these fumes the lecturer showed to be due to the rapid ebullition of the carbonic acid in the water. The lecturer said some difficulty had been experienced in registering the low temperatures now obtainable, as both the air and alcohol thermometers become useless owing to their condition being changed; he therefore used a reflecting galvanometer to register his results. Prof. Dewar then referred to the laws formulated by Boyle, Andrews and others concerning density and pressure, showing that each new law became more complicated because of necessary corrections. This led to an explanation of the term critical point, the critical point of carbonic acid being admirably shown upon the screen by the lecturer, where the moving striæ and sudden change of condition could be distinctly observed. By taking advantage of the phenomenon of heat becoming latent during the vaporization or boiling of liquid carbonic acid a temperature of $-80°$ C. had been obtained, whilst the still lower temperature of $-115°$ C. had been reached by vaporization under a very low pressure. Liquid nitrous oxide had also been used for the same purpose, a temperature of $-90°$ C. being registered, but both these compounds solidify at a lower temperature and are therefore comparatively useless. The Polish chemists, Wroblewski and Olszewski, have obtained the best results, however, by the use of liquid ethylene, a transparent fluid hydrocarbon which is the chief illuminating constituent of coal gas. With the use of ethylene a temperature of $-140°$ C. is registered, which allows of oxygen and nitrogen being solidified, whilst by similarly using the liquid oxygen in further experiments a temperature of less than $-200°$ C. has been obtained and hydrogen converted into a viscous liquid. It is impossible to illustrate these last results in a lecture-room, but Professor Dewar in a series of experiments with liquid ethylene reduced alcohol to a gelatinous condition, in which crystals could be distinguished, whilst bisulphide of carbon was completely solidified. After the lecture he succeeded by careful manipulation of pressure in demonstrating the liquefaction of oxygen, an experiment probably not before shown at a lecture. Though several chemists have stated that they have obtained lower temperatures than those above mentioned, Professor Dewar considered their observations must be wrong, owing to the incorrect marking of their thermometers, as until lately no one had succeeded in solidifying oxygen.

INTERNATIONAL HEALTH EXHIBITION.

Series of Conferences under the Auspices of the Medical Officers of Health, the Sanitary Institute of Great Britain and the Parkes Museum of Hygiene.

At the Conference held on Wednesday, the 11th inst., under the presidency of Mr. Edwin Chadwick, C.B., Dr. J. Sayer Bristowe, F.R.S., read a paper on "Industrial diseases." He said that the investigation of the cause of disease was a subject which had ever engaged and still engaged the choicest intellects in the profession of medicine, for not only did it present the highest scientific fascination, but it was fully recognized that it was in the discovery of the causes of disease that our best hopes of dealing successfully with diseases, either in curing, in mitigating or in preventing them, resided. The special subject he proposed to deal with was diseases due to poisonous or other influences incidental to certain occupations, which could only be escaped, if escaped at all, by the adoption of special precautionary measures. One of the most interesting groups of industrial diseases was that in which injurious effects arose from the slow action of metallic or other inorganic substances, or their derivatives, upon the system. Speaking on chronic lead poisoning, he said this disease was not limited to operatives in lead, such as plumbers, type founders, and manufactures of lead toys, but the general public were by no means free from danger, and that isolated cases, or groups of cases, of plumbism, referable to the drinking of water stored in lead cisterns, to the use of hair washes or cosmetics containing lead, and even to the long continued employment of lead as a medicine, were often brought under the notice of medical men. After referring to the symptoms of chronic lead poisoning, the paper dealt with the subject of chronic copper poisoning, chronic arsenical poisoning, chronic mercurial poisoning, chronic phosphorus poisoning, and the effects of irritants applied to the skin and to the lungs. Apart from the inhalation of solid particles which irritated the lungs into disease, it was certain that many occupations tended to the production of pulmonary phthisis and fatal bronchial affections; and in proportion as the people of a district were attracted to any collective indoor occupation, in such proportion, other things being equal, the district death rate by lung diseases would be increased, for bad ventilation tended to develop among work people a large excess of phthisis. Upon the spread of infectious fevers he thought this might be due in no inconceivable degree to the collection and importation of rags, for the purpose of paper making. In 1865 he made an extensive inquiry into the question of infectious diseases by rags, and more especially among the workpeople engaged in paper manufacturing, and the result was to a considerable extent reassuring, for it appeared that no diseases special to foreign countries had ever been introduced amongst them by the agency of foreign rags, and that, as regarded native rags, the only disease that was ever spread by them was small-pox, and this only rarely. The next disease referred to was what is known in Bradford as the "wool-sorter's disease," which had been ascertained to be the anthrax fever or splenic fever of cattle which prevailed in many parts of the Continent, and also in Asia and America, and was known to spread rapidly from cattle to other animals and to man. The chief sufferers by this disease were those who handled the raw hides coming from abroad, namely wharf labourers, sorters' labourers, and tanners' labourers; but no evidence of the occurrence of the disease could be traced among fellmongers. The paper concluded with a reference to the disease known by the name of "clergyman's throat," to which all habitual or professional speakers and singers are liable, and "writer's cramp," to which persons who had acquired skill in the use of particular groups of muscles were liable, such as the pianist, the swordsman, and others.

Dr. Ord, in opening the discussion, referred to overcrowding, working in ill-ventilated and ill-lighted rooms, as a chief cause of industrial diseases.

Dr. Greenhow said the question the Conference had met to discuss was one which had received very little public attention, although it was second to no other sanitary question of the day, because the mortality produced by "industrial diseases" was very large. Operatives in cotton factories, miners, printers of colour, paper stainers and chaff cutters inhaled dust given off in their operations and were very liable to lung diseases. He hoped the effect of the discussion would be to stir up public attention upon the subject.

Dr. Vacher (Birkenhead), after referring to various unhealthy trades, suggested that employers of labour should be compelled to adopt the most approved scientific processes for rendering shops and warehouses healthy, by which means trade diseases would be very much mitigated and the greater part of them entirely repressed. The Alkali Acts had done a great deal to improve the state of health in the neighbourhood of alkali works, but not much towards improving the health of the workers in the various works. He agreed that dust was a source of great evil, millers, bakers, masons and coal whippers suffering therefrom, but this danger could be greatly diminished by proper ventilation; cases of lead poisoning would be less rare if the precautions suggested by Government Blue Books were taken.

Dr. Ogle referred to the enormous difference in the rate of mortality amongst different trades, and cited statistics to show that the largest death rate was amongst innkeepers, brewers, butchers, cabmen, carters, bargemen, hairdressers and others; and the lowest amongst clergymen, gardeners, farmers, agricultural labourers and grocers.

———

At the Conference held on Thursday, June 12, under the auspices of the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Parkes Museum of Hygiene, Dr. Alfred Carpenter in the chair, the subject discussed was the "Spread of Infectious Diseases, first, through the Agency of Milk, and, next, through other Agencies."

Dr. W. N. Thursfield read the first paper, and stated that the subject was one with reference to which it was specially desirable, on the one hand, not to create undue alarm, and, on the other hand, not to make light of or pass over apparent sources of disease, however improbable they might appear at first sight. It was, however, one of growing importance. Milk was becoming daily more recognized as the staple food for children, as from a variety of causes the proportion of women physically incompetent to suckle their offspring was yearly increasing. The use of milk by adults had of late enormously increased, and, although he could not but consider that to drink milk as a beverage with heavy meals was a grave dietetic error, the modern practice of drinking glasses of milk instead of beer at railway refreshment bars and elsewhere was certainly not to be condemned. The greatest risk of danger from milk was in the fact that the chief consumers were of an age when the body was most susceptible of taking disease, and the consumption of unboiled milk might literally be said to bring the consumer into closer connection with the animal from which the milk was drawn, and always to some extent and often most intimately with the family and domestic arrangements of, at least, one householder, and often two. Since Dr. Ballard's report of an epidemic of typhoid fever in Islington in 1870, when attention was called to the matter, records of about a hundred epidemics alleged to be traceable to milk dissemination had been published, and others, not published, had been noted. Making allowance for all doubtful cases it might be accepted as an absolute fact that epidemics of typhoid fever and scarlet fever had been repeatedly disseminated by milk, and there was very strong evidence that diphtheria had been so disseminated. He believed there was very little accurate knowledge as to the mode in which milk became a vehicle for the germs of infectious disease. To effectually prevent milk epidemics precautions were necessary, first, at the house of the consumer, secondly, at the milk shop of the retailer, and, thirdly, at the dairy farm of the wholesale purveyor. Upon the first point he recommended boiling of milk, as it was a well-known fact the consumers of boiled milk had, as a rule, escaped in all milk epidemics. Upon the second point, he suggested that urban sanitary authorities should have the power to stop the sale of milk consigned from any particular farm on the occurrence of any infectious disease, and that it should be incumbent on retailers, when required by the sanitary authorities, to furnish a list of their customers. Upon the third point, he suggested that the premises on which the business of a milk purveyor was carried on should be registered with the local authority, and every registered dairy should be provided with a plentiful supply of good potable water for the use of the dairy and cows. The dairy used for storing the milk should not be subject to animal effluvia of any kind, and should be satisfactorily drained, and not used for general domestic purposes. Milk should not be transmitted for sale when presenting any marked deviation from ordinary appearances, in either colour, smell, or general condition, or when obtained from an animal manifestly the subject of constitutional disease, acute disease, or infectious disease of any kind. On the occurrence in the person or family of anyone employed about the cows or the dairy, of any eruptive or infectious disease at all, or of any throat complaint affecting three or more persons, the affected individuals should be isolated, and the fact notified to the health officer. He believed inspections might be so carried out that the inspector would come to be looked upon, not as an interloper only borne with so far as the law demanded, but as one in a position, under certain circumstances of disease incidence, to give advice, valuable from a commercial, as well as from a sanitary point of view. Whatever differences of opinion there might be on technical points and matters of detail, he thought that all who had carefully considered the subject would have formed a decided opinion that the adoption of regulations as to the sale of milk should be incumbent on local authorities, and not permissive, as at present, and that the regulations should be applied at the producing as well as the distributing depôts.

Dr. W. H. Corfield next read a paper on "How Infectious Diseases are Spread." He thought the atmosphere was the most universal medium of communication, though some poisons were more readily conveyed in this way than others. Poisons of several diseases might be conveyed by means of clothing, and laundries were often the agencies of dissemination. An instance was given where chicken pox had been communicated by means of letters. Drinking water was a most important vehicle for conveyance of cholera and enteric or typhoid fever with dysentery in hot climates; and diphtheria might be spread in this way. In some instances it had been shown that flies conveyed the poison of infectious deseases.

Professor de Chaumont, F.R.S., thought there could be no doubt that milk was a vehicle of communicating typhoid and enteric disease, and in a smaller degree also scarlet fever and diphtheria, although this view was by no means shared upon the Continent. Before attributing disease to milk the cause should always be thoroughly investigated, because it occasionally happened that it was due to other causes.

Mr. Shirley Murphy said in practice it was impossible to detect these poisons in milk in such a manner as to enable the investigation to be of use in stopping an outbreak. The only way in which it could be known whether milk was infected with the germs of scarlet fever or enteric fever was by the effect it produced on the people who drank it, and it was an unfortunate thing that medical officers of health were unable to prevent infection until a certain number of deaths had occurred. He agreed with the readers of the papers that there was less chance of infection to persons drinking boiled milk.

Dr. Flemming, Dr. George Wilson, Dr. Priestly, Dr. Pringle, Dr. Armstrong, Dr. Charles West, Dr. Anderson, Mr. Burns and Dr. Dudfield having also addressed the meeting,

The Duke of Buckingham (President of the International Health Exhibition) said this question was one in which he took an especial interest, and he hoped the result of these Conferences will be to draw the attention of the public to the subject. One of the most remarkable effects of that Exhibition would, he trusted, be the elucidation of a vast number of sanitary questions which affected the whole of the inhabitants of this country. The question of sanitary legislation was no doubt one which pressed more and more upon the attention of the public, and it came home to the labourer as well as to the rich man. He quite concurred in the view which had been expressed, that a more general control over sanitary matters was wanting in the country as much as in large towns, and Parliament must before long be called upon to deal with this question. The object of those Conferences was to bring forth the evils which now existed, and to elicit opinion as to the general grounds upon which they might be dealt with.

After a few remarks from the Chairman, the Conference adjourned.

At half-past 5 o'clock Miss Smithard gave a lecture on Dairy Management, with a practical demonstration of butter making. She dwelt especially on the necessity for absolute cleanliness in the dairy, and all vessels appertaining to it, and on attention being given to temperature, a slight rise or fall of which would prevent the formation of the butter. The Normandy and Danish systems of butter making were described, and some very nice looking butter was produced at the conclusion of the lecture, and worked up into proper form for market.

Lord Reay, who occupied the chair, in proposing a vote of thanks to Miss Smithard for her admirable lecture, expressed a hope that English farmers would pay more attention to dairy work, as there was no reason why England should not make the best butter in the world, and even export it to foreign countries instead of depending on them for her own supply.

The next Conference of this series was held on Friday, June 13, the Earl Fortescue in the chair. The Chairman said that in the promotion of sanitary reform affecting the widespread work of sanitation, it must be inevitable that individual liberty and the rights of property must to a certain extent be interfered with for the public good. He should listen attentively to the arguments for and against a novel, but by no means unprecedented, extension of that interference in the shape of compulsory notification of the existence of infectious diseases. It was for the advocates of any compulsory interference with individual liberty or with the rights of property to justify exceptional legislation for that purpose.

Dr. Alfred Hill read a paper on "The Notification of Infectious Diseases: its Importance and Difficulties." The paper, after referring to the value of compulsory notifications of births and deaths, dealt with the importance of sanitary authorities having the earliest possible information of disease in order that its spread might be prevented. The objection to voluntary notification was that it was incomplete, and consequently useless for the prevention of epidemics. The value of complete notifications was well seen in Birmingham during the early days of the present visitation of small-pox. After referring to the various objections to the proposal, namely, the compulsory character of the duty, the antagonism between medical practitioners and medical officers of health, the betrayal and destruction of that confidence which was necessary between doctor and patient, and that notification would be injurious to business, the lecturer concluded by expressing his opinion that these objections were for the most part of a hypothetical and speculative character, and that its principal opponents were persons who had no actual experience of its working. On the other hand, both the public and the medical profession in the thirty-eight towns where it had been already submitted to a practical test accepted it with satisfaction.

Dr. Alfred Carpenter also read a paper on the same subject, but dealt more particularly with the right and duty of the State to enforce the notification of infectious diseases. Having detailed the history of the progress which had been already made in the direction of notification of disease, he said the object of notification was not simply a registration, but a repression of disease, and if the repression was brought about the means whereby it was done was of no consequence. He suggested that they should try to get a general Act which should apply the same law as to infectious disease as now applied to contagious diseases among animals. If after a time the general application of such a law failed in its effect there would then be a sufficient reason for placing penalties upon the whole medical profession for not performing that which could only be regarded in the light of a moral duty. The power of instituting prosecution for not carrying out the law should be entrusted to the Medical Council of Great Britain, so as to get rid of the possibility of professional rivalry and vindictive or malicious action.

Mr. W. Blyth thought those who wished for compulsory notification had to make out a very strong case before it could be obtained. He believed that a case had been made out for some alteration, though he could not go so far as the readers of the papers. Some medical gentlemen imagined that compulsory notification would altogether stamp out infectious disease, but this was a fallacy, as many persons were every day walking about the streets suffering from scarlet fever, who did not even know they were suffering from the disease.

Dr. Carter (Liverpool) did not believe that the private Acts now in force would work without serious modifications, and that they did not control the spread of infectious disease more than it was controlled in other towns without such Acts. In support of this view he quoted statistics to show that in towns where the Act was in force the death rate had not been in the slightest degree reduced.

Dr. Armstrong (Medical Officer of Health of Newcastle-on-Tyne) maintained that since the Act had been in force in Newcastle great improvement in the health of the inhabitants had taken place.

Mr. William Young (Secretary to the Society for the Compulsory Abolition of Vaccination) objected to compulsory notification, and suggested that as zymotic diseases were being stamped out by the present sanitary arrangements they should be tried a little longer before legislation was attempted. He believed the bogie of infection had been raised up to serve some purpose.

Dr. Mahomet thought the system of notification and isolation would not answer; for in the case of measles the most infectious period was during the first four days, when the disease could not be diagnosed. Typhus had been almost banished by improved sanitary arrangements, and with regard to small-pox that could be prevented by vaccination. Isolation might do good in the case of scarlet fever if every case could be dealt with, but many persons had it without knowing it.

Dr. Dudfield spoke in favour of notification of infectious disease, and referred to the good effects of the system as carried out in Kensington.

Mr. James Bailey (Secretary to the Vigilance Association) urged that a good case must be made out before such a measure was attempted to be forced on the poorer classes, for he did not think sanitary officers would attempt to meddle with the rich. He agreed with Dr. Carter that the laws which were in force in certain towns compelling compulsory notification had not resulted in any marked diminution of disease.

Dr. N. Hardy, as a medical man, objected to the principle of compulsory notification, and referred to the great plague of London, when compulsory notification was necessary, as an instance that it would not stamp out disease.

Professor Corfield said it was absurd to say that the notification of epidemic diseases did not prevent the spread of disease. In such cases as measles, schools could be closed directly the disease was known to exist, and only recently this disease was checked in St. George's, Hanover Square, in this way. He objected to the liberty of the subject to spread infectious diseases.

Dr. Charles West testified to the immense advantage of notification, but did not go into the question of compulsion. He had seen the evil arising from concealment in a health resort in the South of France, and the diminution of contagious disease where notification was practised.

Dr. Taaffe (Brighton) said he could have prevented the spread of typhoid fever amongst ninety families, i the first case, which arose from contaminated milk, had been notified to him. He was in favour of compulsion.

The Chairman, in summing up the discussion, said it seemed to him that a case had been made out for compulsory notification of disease, but after the difference of opinion which appeared to exist amongst the medical profession he did not think a case had been made for compelling medical men to notify cases which came under their notice, but that the responsibility should lie on the householder. As an old sanitary reformer he could not conceal from himself that the fullest notification did not always prevent the spread of zymotic disease, whilst in other cases where favourable food conditions and cleanliness prevailed such diseases did not spread.

At the Conference on Saturday, Lieutenant-Colonel Sir J. M'Garel Hogg, Bart., K.C.B., M.P., in the chair, two papers were read: (1) "The Disposal of the Dead," (2) "Cremation." The first paper was read by Mr. A. Wynter Blyth, who said the term "disposal of the dead" in its popular narrow limitation meant simply the disposal of human remains, but, taken in its widest significance, included the disposal of everything which had had life, whether vegetable, animal, or human. He should confine himself to the methods of dealing with human remains, viz., simple exposure, burial in the ground, in the sea, cremation, and embalmment, under which head might be included all kinds and methods of preservation. The first method only existed among a few races and tribes, and as to the second, viz., earth burial, its origin had been confidently ascribed to sanitary precautions, but, so far as he could see, the study of the habits and methods of thought of primitive man by no means countenanced this view. If this plan were to be continued he would suggest that only one body should be buried in a grave at a minimum depth of six feet, that the use of vaults should be abolished, that no irremovable headstones or monuments should be allowed, and at the end of a certain number of years, reversion to agricultural purposes. With regard to burial in the sea he thought the same objection applied to that as to cremetion, that it too effectually disposed of the body, rendering certain crimes difficult of detection. With regard to cremation, he said the practical aspects had recently received a fresh impetus in the form of a declaration by Mr. Justice Stephen to the effect that there was nothing in the English law forbidding cremation, and by a Bill which was introduced into Parliament with the object of enacting regulations so as to insure that the practice of cremation was not applied to the concealment of crime. As to the objection against cremation that the discovery of organic poison in cases where murder had been committed would be impossible, he suggested that anyone desiring the cremation of a friend or relative should give notice to the coroner, who would thereupon direct a medical man to at once visit the case, make a *post-mortem*, and give the coroner a written report, and upon this report, if favourable, the coroner would give his certificate for cremation. The expense of the medical examination would of course fall on the relatives of the deceased. As to embalmment, he thought all persons found dead in the streets, and not identified, should be subjected to this method, and remain unburied for many months in order to give an opportunity of solving the problem of what were called "mysterious disappearances." In conclusion, he suggested that funerals should take place between 4 and 8 a.m., and that unnecessary expense should be dispensed with.

Mr. Wm. Eassie, C.E., next read a paper on "Cremation." He said that upwards of fifty lectures had been publicly delivered upon cremation since the foundation of the Cremation Society of England in 1874, and the general consensus of opinion was in favour of the introduction of the practice. With regard to the only tangible objection made to cremation, that it might serve as a screen for poisoners, he thought the conditions enforced by the Cremation Society before allowing the use of their Crematorium at Woking would fully meet the case. The following were the conditions:—"(1). An application in writing must be made by the friends or executors of the deceased—unless it has been made by the deceased person himself during life—stating that it was the wish of the deceased to be cremated after death. (2). A certificate must be sent in by one qualified medical man at least, who attended the deceased until the time of death, unhesitatingly stating that the cause of death was natural, and what that cause was. (3). If no medical man attended during illness, an autopsy must be made by a medical officer appointed by the society, or no cremation can take place." Crematories were now in full use in Gotha, Milan, Rome and other places, and during the last few years some five hundred bodies had thus been withheld from lingering corruption. Cremation societies, with thousands of adherents, existed in France, Holland, Sweden, Spain and Portugal, and the adoption was merely a matter of time in America. Cremation could be performed within two hours at the expense of a few shillings, and an ordinary body reduced to some three pounds weight of pure white ashes. The crematory chosen by the English society was built upon the Gorini pattern, a plan of which was exhibited, one of its chief advantages being that the commonest fuel could be made use of. On one occasion he destroyed 120 lbs. weight of a carcase at Woking, chiefly with a few faggots of wood, at a cost of $3\frac{1}{2}d.$ each. After referring at some length to the dangers attendant upon burial, and the advantages of cremation, especially in cases of persons who had perished from disease, the paper concluded, with the expression of a hope that some State regulations would soon be formulated, such as were contained in Dr. Cameron's Bill, and such as had been published by the Cremation Society of England.

Dr. Cameron, M.P., thought this subject was one of the most important that could well be discussed in connection with a Health Exhibition. From a report published in 1851, it appeared that in England and Wales as many persons died and were buried without any certificates as to death being given, as died in the metropolitan district in the course of three months, and in England, Scotland and Ireland the number of persons who were buried without a certificate in a year amounted to as many as died in the entire metropolis in five months. With regard to cremation, he thought it was very hard that if a person wished to be cremated he should not be allowed to have his wish, though he did not believe that cremation would become general for some time yet. If cremation was legal Government had no right to interfere in the matter. As to the objection that it would shield crime, he thought that was disposed of by the statement he had already made as to the numbers who went to their graves without any certificate of death.

Sir Spencer Wells, Bart., was of opinion that the present style of burying the dead perpetuated disease, and that cremation would be a great boon. He was glad to see that this question had been taken up by the Commissioners of Sewers, and no doubt cremation would soon be adopted.

Dr. Farquharson, M.P., referring to the discussion which had taken place in Parliament upon the subject, said the supporters of cremation had been twitted by Sir W. Harcourt that they had not the public at their back. Having said that, Sir William thought he had crushed the movement; but he must have been surprised to find that seventy voted in favour of the Bill, and that the Press almost unanimously supported the movement. The growth of opinion upon the subject was very rapid and as it had been held that cremation was legal. No doubt when the subject again came before Parliament it would meet with more success.

Rev. Brooke Lambert strongly advocated cremation and denied that it was contrary to religion. If it were supposed that the actual carcase of an individual comprised the title deeds to resurrection, then they came to this extraordinary conclusion, that the martyrs, who of all men in the world were supposed to have the best right to resurrection, were the very people who had lost their title deeds. Those who objected to cremation on religious grounds were the people who had least considered the subject.

Dr. Bartlett also supported cremation, dwelling chiefly upon the chemical aspects of the question.

After a few remarks from Dr. Pringle,

Captain Douglas Galton said, no doubt cremation had many advantages, but it would be a very long time before it became universal in England, and, therefore, sanitarians would do well to pay some attention to other modes of disposing of the dead.

Dr. Dudfield was glad to find the religious and sensational objections to cremation were so far on the decline that there was a chance of the question being discussed and settled upon its merits in the not far distant future. He recommended the erection of public mortuaries and the compulsory removal of dead bodies thereto, more especially from poor and crowded neighbourhoods, as there was no doubt that infectious diseases were often spread by dead bodies.

Dr. A. Carpenter, while not being prepared to go the length of saying the time had arrived for cremating all bodies, thought persons who had died of infectious diseases ought to be cremated.

Mr. Liggins strongly objected to cremation and urged that millions outside that Conference looked with horror upon such a radical change in the disposal of the dead.

Dr. Gibbons also spoke against cremation, and after a few words from Mr. Hodgson and Mr. Smith,

The Chairman said he entirely agreed with the suggestion as to the desirability of having public mortuaries and that in large blocks of artizans' dwellings a place should be provided for the dead.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, June 12, Mr. T. S. Dymond, Vice-President in the chair.

A paper was read by the Honorary Secretary (Mr. Wyndham Dunstan) on "A Process for the Separation of Chlorides, Bromides and Iodides."

The paper was followed by a discussion in which the Chairman, Messrs Blain, Cripps, Elliott, Lowe and Steward took part.

The thanks of the meeting were voted to Mr. Dunstan.

The Reporter on Practical Pharmacy, Mr. R. A. Cripps, then read a Report on "Concentrated Infusions and Decoctions."

The Report gave rise to a discussion in which the Chairman, Secretary, Messrs. Elliott, Job and Short joined.

After some miscellaneous business had been transacted, the meeting adjourned.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.

In the Second Court at the Sheffield Town Hall, on Wednesday, June 11, before Mr. T. Turner and Mr. H. J. Wilson, Thomas Wilcock, provision dealer, of 81, South Street, Park, was summoned for that he, "on the 9th February did unlawfully sell by retail to one Ann Castle, certain poison, to wit, opium, being poison within the meaning of the Pharmacy Act, 1868, which poison, when sold, was contained in a bottle, and which bottle was not distinctly labelled with the name of the article and the word 'poison,' and without the name and address of you, the seller of such poison, contrary to the form of the statute."

Mr. Flux, of the firm of Messrs. Flux, Son, and Co.; London, solicitors to the Pharmaceutical Society, appeared on behalf of the prosecution, and Mr. S. B. Auty defended.

Several Sheffield chemists were in court during the proceedings, and the case was watched with much interest.

In opening the case, Mr. Flux said he would do so as shortly as possible and would not say one word to create prejudice. But he should ask to be allowed, at another stage of the proceedings, to make a few statements on public grounds. The prosecution was under clause 17 of the Pharmacy Act, 1868, which declared "it should be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, vessel wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article, and the word 'poison,' and with the name and address of the seller of the poison," and also that "any person selling poison otherwise than as herein provided shall, on summary conviction before two justices of the peace in England, be liable to a penalty not exceeding £5 for the first offence." The charge against the accused was that he sold poison in a bottle without labelling it; amongst the contents of the bottle was opium, or a preparation of opium within the meaning of the schedule, The sale was made to a Mrs. Castle, who had applied to the defendant for some "infant's mixture." A portion of the contents of the bottle was administered to an infant child by the mother; the infant died, and an inquest followed.

Mr. Turner: Is it necessary to bring this in?

Mr. Flux: Yes; because I am going to bring in evidence the depositions of the accused at the inquiry.

Mr. Dossey Wightman, Coroner, was then called and examined by Mr. Flux. He produced the depositions of the defendant, who gave evidence at the inquest on the 19th February on the body of Frederick Castle. He stated, amongst other things, that he had known the parents of the deceased about three years. He remembered the mother calling upon him, and saying she had a child which was poorly. She had with her a child, between two and three years of age, with its throat tied up, and she said that was also poorly. She asked for some mixture—he believed she specified it "infant's mixture"—and said she wanted it for the child who was with her. He replied that he had a mixture which he thought would do the child good. The woman purchased a quarter of an ounce. He read the dose to her from the label on the bottle which he had, and told her about ten drops would be the proper proportion to administer to the child. He did not put a label on the bottle which he gave the woman. He did not know the mixture contained any preparation of opium. The label on the bottle in his possession did not say "poison." He was not told the age of the child, but judged from its appearance.

Cross-examined by Mr. Turner: I understand you to say that the child which died was not the baby for whom this stuff was sold.

Mr. Wightman: The woman, according to her evidence, applied for the medicine, with a child with her, but this was not the child on which the inquest was held. The inquiry was concerning the baby, which was at home with her husband.

Mr. Turner: Not the child taken to the shop?

Mr. Wightman: No; and for aught I know that child is living now.

Mrs. Sarah Castle, the wife of William Castle, cutler, living in Leader Road, Hillsbro', examined by Mr. Flux, spoke to the purchasing the mixture from the defendant. She asked him if he had any stuff to soothe a baby, saying that she found the druggists' shops were closed. That was on a Saturday. She did not know the day of the month. The child died six days afterwards. The defendant told her he had some "infant's mixture," saying it had done many children good; it would, he said, soothe them. She wanted it for both children, but more so for the babe. She fetched a bottle and purchased a pennyworth of the mixture. She was told to give the babe ten drops and the other child half a teaspoonful, which she did as soon as she got home. The bottle was not labelled.

Cross-examined: I am twenty-two, and have been married about three years. A neighbour suggested that I should get some soothing syrup, and I was told to go to a druggist, but they were all shut up. When I went to the defendant, I asked for some "infant's mixture," telling him what it was for. I did not lead him to understand that I wanted the mixture for the girl that was with me. I said distinctly that I required it for the babe, and I gave it ten drops, as desired, when I got home, in some warm water and with some sugar. On the following Monday I again gave the babe some mixture. It did not seem to take any effect upon the child.

Mr. Turner: We do not seem to get any nearer to the point.

Mr. Wilson: Do you suggest that the man intended to poison the child? The questions would be more to the point if you would show that there was not opium in the bottle, or that it was labelled.

Mr. Auty: I think I have a right to put these questions. I want to get from the mother the effect the mixture had upon the child. If she found that it had a pernicious effect upon the child she should have stopped administering it.

Mr. Turner: But that would not affect the question whether there was poison in it.

William Castle, the father of the deceased child, examined, spoke to handing the bottle which had contained the mixture to the police. He found it in the cupboard. There was no label upon it. There were a few drops in it when he handed it to the police.

Cross-examined: I am twenty-seven years of age. I know nothing about my wife going for the mixture, but I asked her to get something for the baby, and I saw her give it the drops.

Police-constable Thornton, examined, stated that he received the bottle from the last witness on the 19th February. It then contained some ten or twelve drops. He handed the bottle to Mr. Allen, the Borough analyst. Witness also saw the larger bottle. Both were produced at the inquest.

Mr. Alfred Henry Allen, Borough Analyst, deposed that he was examined at the adjourned inquest. Previous to that he had analysed the contents of the large bottle produced. There were about five drops of the mixture in the lesser bottle, and the chief constituents were the same as in the large one, so the presumption was that the liquids were identical. The chief constituents were rhubarb, magnesia, spirit, some aromatic waters, and laudanum, or a preparation of opium. Whether introduced in the form of opium or not he could not say. Neither could he say whether it was introduced in the form of a tincture called laudanum.

Cross-examined: I am not certain that the small bottle contained opium. The quantity was too small for me to to be able to ascertain. I can swear that the large bottle contained opium.

Mr. Flux intimated that this was the conclusion of his case.

Mr. Auty asked whether he had a case to answer. Personally he thought there was nothing to answer. If their worships said there had been sufficient evidence given for the case to be proceeded with, he would say something in mitigation of the penalty.

Mr. Turner: We should like you to proceed.

Mr. Auty then called,

Henry Linley, Oakhill Road, Nether Edge, who said he formerly carried on the business of a chemist and druggist on Sheffield Moor. He was not a member of the Pharmaceutical Society or a Pharmaceutical Chemist. When in business he made up a mixture, and recognized the label on the larger bottle produced as similar to those he used for distinguishing the preparation. He made up two similar mixtures. One, which contained a small portion of laudanum, he sold to his retail customers; and the other, which contained no laudanum, he kept for wholesale purposes. He could not say whether the mixture in the larger bottle contained laudanum or not, seeing that it was between four and five years since it was sold. He should not sell the mixture containing laudanum to wholesale customers. It was not necessary to label a preparation "poison" if it contained only a small proportion of laudanum; but if the mixture went as a preparation of opium then it would be necessary to label it so.

Mr. Flux: You will not say that five years have not passed since the larger bottle left your hands?—No.

Nor that the defendant has not again and again had it refilled at the grocer's?—No.

Mr. Wilson asked Mr. Wightman whether the defendant positively admitted or swore at the inquest that the woman's bottle was filled with stuff from the larger bottle produced.

Mr. Wightman replied that that was his impression at the time. The larger bottle was produced by the defendant, and he admitted that the stuff in the lesser bottle was the same, but he did not remember whether the man said it was filled out of the larger bottle into the smaller one.

After a short consultation the magistrates fined the defendant 20*s.* and the costs, in all £3 1*s.*

Mr. Flux, addressing the Bench, said, Now that the case has been disposed of, I ask permission to mention that the Pharmaceutical Society of Great Britain have instructed me to conduct the prosecution. The 15th Section of the Pharmacy Act imposes on the Society duties in regard to offences under that section, but there is nowhere imposed on the Society the duty of prosecuting in cases of this kind. The Society has received information, on which reliance can be placed, that sales of poisons not labelled as contemplated by law for the protection of the public are made in this town, to a serious extent, by unqualified persons, and having that information the Society has, for the purpose of directing local attention to the state of things and especially to the law on the subject, charged me with the conduct of this prosecution. It will be seen on examination of Section 17 that any person may be prosecutor where an offence such as this has been committed, and I venture respectfully to suggest to your worships, sitting as magistrates of this town, that it may be for the public welfare that the attention of those who in this town are charged with the administration of the law shall be especially directed to the offences against the provisions of the 17th Section with a view to such prosecutions by the local authorities as will secure that the breaches of the law shall be discontinued.

Mr. Wilson: Mr. Flux, I entirely agree [with every word you have said.

Reviews.

GRUNDRISS DER PHARMACOGKNOSIE. Von F. A. FLÜCKIGER.*

The object of this little work appears to be to meet the need of medical and pharmaceutical students for such an elementary book on materia medica and pharmacognosy as shall contain all the useful information which it is imperative for them to know and remember, but shall exclude such matter as is only valuable for reference. It is of course intended for those to whom the German Pharmacopœia is the standard text-book, and consequently a number of drugs not commonly met with in English pharmacies are described in its pages. Besides those occurring in the German but not in the British Pharmacopœia a number of drugs which are of recent introduction, such as cola nuts, coca, curare, gelsemium, quebracho, etc., receive a full share of attention. The classification adopted in the 'Grundriss' differs from that of the larger work by the same author, 'Pharmakognosie der Pflanzenreiches,' in the drugs being arranged not according to their nature, but according to the natural orders to which they respectively belong. The awkwardness of finding the root of aconite, for instance, in one part of the same volume and the leaf in another part is thus avoided. In the present volume the cryptogams are placed first, then follow the phanerogams, and lastly the products derived from the animal kingdom. The classification of the phanerogams is not that followed in Great Britain, the dicotyledons being divided into *Choripetalæ*, including all which are either without petals or have them distinct, and *Sympetalæ*, comprising all which, in this country, are comprised under *Corolliforæ*. Thus *Myristicaceæ* and *Lauraceæ* come near *Magnoliaceæ*, and *Euphorbiaceæ* is placed between *Rhamnaceæ* and *Umbelliferæ*, an arrangement which would prove somewhat puzzling to many English readers, but which nevertheless presents some advantages from the point of view of materia medica, as well as from a botanical standpoint. The natural system is not, however, carried out with regard to the animal products; these being few in number are arranged alphabetically.

As an introduction to more extensive treatises on materia medica, this little volume will doubtless be most welcome to students and will serve to give a good foundation in the subject. If the author has devoted space to the history of the drugs which would perhaps have been better devoted to adding matter of more practical use in everyday life, it must be remembered that, the German tendency to prolixity being taken into consideration, the book is a marvel of conciseness and useful information of the kind that the student requires in commencing the study of materia medica.

In the majority of cases the information has been brought up to the latest date, but the notices of substitutions or falsifications of drugs are less full than might have been expected in a work of this kind. Thus we find no notice of Japanese aconite root, nor the means of detecting the various adulterations of saffron and belladonna root and digitalis, nor of the commercial varieties of jaborandi and jalap, ergot and cantharides, etc. Nevertheless, the book contains a large amount of information clearly and concisely put, and will probably give great satisfaction to the class of readers for whom it is intended.

In a few points, perhaps, one may venture to differ from the learned author, and if these are indicated here it is only with a view that the reader may recognize that there is a difference of opinion on these points. *Laminaria Cloustoni* is described (on p. 1) as a peculiar form of *L. digitata*, Lamoroux. On reference to the author's larger works, however, it will be seen that a better way of stating the facts of the case would be to say that it is a distinct species, formerly included erroneously under *L. digitata*, Lam. Dammar resin presents all the characters of a dipterocarpous product, although it is true that it is usually attributed to coniferous trees. The Arabian aloes possesses different chemical characters from that of Socotra and can scarcely be the product of *A. Perryi*, as suggested by the author.

WATER AND WATER-SUPPLIES, AND UNFERMENTED BEVERAGES. By JOHN ATTFIELD, Ph.D., F.R.S.*

Included in a series published under the auspices of the Executive Council of the International Health Exhibition is a volume by Professor Attfield, treating of water and water-supplies and unfermented beverages.

The work is intended to furnish those whose interest in such beverages is more than superficial with information

* London: W. Clowes and Sons. 1884. International Health Exhibition Handbook. Demy 8vo. Pp. i.-x., 1-114. 1*s.*

which is to them not generally easy of access, or is unintelligible when obtained. We congratulate the author on the simple and lucid manner in which he has placed before the unscientific reader the leading chemical and physical properties of water and scientific explanations of certain phenomena connected therewith.

Most interest will, perhaps, be taken in the chapters on the natural water supplies, dealing with the source, the methods of preventing contamination and the means of purifying water from suspended and other impurities: these are very complete. Mineral and aërated waters are described in Section II. But the fourth section of the work, treating of teas of various kinds, coffee, cocoa, chocolate and milk is certainly no less worthy of attention, although it occupies less than one-third of the whole work. We recommend the chapter on tea to the perusal of the fairer sex, who might refresh many hard-workers with a cup of that beverage in which the aroma was more and the tannin less perceptible than is now usually the case. The low price at which the book is published places it within the reach of all who are interested, and will, we think, ensure it the reception it deserves.

Correspondence.

Ethics and £ s. d.

Sir,—When "Ethics" get mixed up with prices they need cautious handling. Criticisms of our neighbour's system of business are more apt to exhibit our own jealousy than a desire for his reformation. They too often overlook the fact that the public good is the true *summum bonum*, and—other things being equal—that "cheapness" is a quality much desired by the public. Pharmacists are no exception to the economical doctrine that he who gives a certain service for 1*s.* is a more profitable public servant than he who gives the same service for 1*s.* 6*d.*; and pharmacy offers no exception to the rule that no good thing can be, in common phraseology, cheap. The public apply both dogmas with tolerable discrimination, and they have been shrewd enough to discover in the matter of medicine that the best is generally the cheapest; accordingly we see that the most successful dispensing businesses are conducted on the 1*s.* 6*d.* system, not upon the 1*s.* system.

The much attacked custom of dispensing by doctors has its origin and its justification in the same principle of public accommodation. The majority of patients cannot afford to pay guinea fees, and the majority of doctors are obliged to meet their medical necessities on other terms. No one imagines that if doctors had their choice they would elect to do double duty for small remuneration, instead of confining themselves to a purely consulting practice acknowledged (not paid for!) by handsome fees; and probably no patient supposes he is equally well served for the smaller cost. These arrangements need no justification; the only wonder is that anybody should think them fit objects for animadversion. When a pharmacist, suffering it may be from a painful insufficiency of that kind of business for which he has qualified himself at much pains and expense, finds fault with medical men for dispensing their own prescriptions he puts himself in a false position analogous to that taken by the latter when they rail at "counter prescribing" as the cause of their lack of fees. Each usage is a necessary concession to a legitimate public want.

Dispensing by medical men has, however, other phases than the typical one referred to in the above lines. Often the doctor enters into an unrecognized partnership with a pharmacist, which is always more or less objectionable. Whenever this happens there must be a pharmacist at least as much to blame as the doctor, and there is no case for accusation on the side of the one vocation against the other. It would be harsh to say that such Kilmainham understandings are immoral, for no doubt many honourable men have been parties to them; but they certainly operate unfairly, and, I think, they are disloyal. They are unfair as interfering with free competition, diverting customers, often against their will,—*experto crede*,—to the doctor's colleague, and because they make unfair distinctions in favour of the doctor's patients as against other customers. The former, in effect, receive a rebate on their medicines as a contribution to the costs of medical attendance. They are disloyal because they tend to perpetuate a system which is injurious to pharmacy.

But what shall be said for the latest development of the pharmaco-medical combination,—one which, I am told, prevails extensively in the suburbs of London? I have it on good authority that it is a practice with certain medical men, who profess to advise patients gratuitously, to inscribe on the prescriptions given in such cases the words "Acct. 2*s.* 6*d.*" (the amount being varied at discretion). This means that the pharmacist to whom the prescription is taken is to charge the patient 2*s.* 6*d.* (the ordinary price being, say, 1*s.* 6*d.*) and he is to credit the difference to the benevolent doctor who gives advice gratis to the poor!

I make no comment. If the naked deformity of the transaction does not ensure reprobation, neither would the strictures of

Outis.

Oil of Limes.

Sir,—Since the appearance of my remarks on Trinidad Oil of Limes in this Journal (p. 1005), I have received a letter from the Montserrat Co., Limited, in which I am informed that the statement therein quoted by me from Mr. Prestoe's letter, to the effect that "the plan is adopted in Dominica and Montserrat of crushing the limes, and then, on the attainment of a large quantity of pulp, proceeding to boil down, or distil," is quite incorrect, at all events as respects Montserrat. The writer adds the following remarks:—"We feel sure that Mr. Prestoe made this statement in ignorance, and would be the first to wish to correct it. The whole of the Montserrat lime essence is made upon our estates, which probably turn out three times as much as all the rest of the West Indies put together. All that we manufacture at present is hand made, neither submitted to boiling or distillation, and the quality is universally admitted to be the finest in the market." I have not had the opportunity of examining a sample of the oil of limes prepared by the Montserrat Co., but of all the samples met with in commerce that I have examined, not one would bear comparison in odour with the specimen of Trinidad oil of limes of which I wrote. In fact I am told that the latter was not recognized as oil of limes by the usual buyers of the article, which is sufficient evidence for my statement that it differs from the ordinary oil of limes.

The Montserrat Company's letter indicates, however, that the difference I have observed is not due to the reason assigned by Mr. Prestoe, and that there must be some other cause for it. I should be the last to wish to publish incorrect statements, or to injure the reputation of any genuine commercial product, and should be glad, therefore, if you will afford me the opportunity of publishing the above statement. If the product of the Montserrat Company has the same fragrance as the Trinidad specimen that I examined, there can be no reason why it should not still be considered the finest in the market.

E. M. Holmes.

Erratum.—In the report of Mr. R. Reynolds's remarks (p. 1016, col. ii., line 4), *for* "those who had *no* great reason to complain of the condition of pharmacy," *read* "those who had *so* great reason," etc.

T. J. Wilkes.—(1) *Viburnum Opulus.* (2) *Stellaria Holostea.* (3) *Corydalis claviculata.*

J. Hutchinson.—(1) *Carex riparia.* (2) *Lolium perenne.* (3) *Bromus sterilis.* (4) *Hordeum pratense.* (5) *Serrafalcus mollis.* (6) *Festuca ovina.*

"*Pertinctus.*"—Tinctura ferri pomata is an official preparation in the Pharmacopœa Germanica. It is made by dissolving one part of the official extractum ferri pomatum in nine parts of cinnamon water. The extract appears to be essentially a crude malate of iron made by digesting finely divided iron in apple juice at the heat of a water-bath until there is no further evolution of gas.

H. Brooks.—It is not advisable to accept as true all the statements made by customers with respect to the prices charged at other shops.

Communications, Letters, etc., have been received from Messrs. Ward, Ashwell, Humphrey, Botterill, Merck, Amo, H.

"THE MONTH."

The announcement of an electric battery which yields residual products of more value than that of the original materials used,—in which, in fact, the electric current generated is a kind of bye-product,—would, if capable of sustained demonstration, appear to solve one of the most difficult problems in the practical application of electricity. The Lalande battery, on behalf of which this claim is seriously put forward, is described as being formed of a series of cells, each one consisting of an iron tray containing oxide of copper, over which, but not in contact with it, is a zinc plate, the remainder of the tray being filled with solution of caustic soda. So long as the circuit remains open no action is set up; but upon the electric circuit being completed, action takes place between the oxide of copper and the zinc, the copper being reduced to the metallic state and oxide of zinc being formed. A battery made up of forty-eight such cells, each one foot square, is stated to give a current of between fifteen and twenty ampères, the electro-motive force being a little under one volt, and to be capable of supplying the current required for fifteen incandescent lamps of ten-candle power each. After the battery is exhausted the zinc oxide can be recovered from the soda solution and is estimated to be worth 25 per cent. more than the metallic zinc from which it is produced, whilst the copper oxide can be regenerated at a small cost. This claim is so far confirmed that the first practical application of the battery was by Mr. J. B. Spence, who was interested simply in the production of oxide of zinc more cheaply than by the ordinary process; but it is evident that the introduction of the battery to any considerable extent for electric purposes would tend to lower the value of the residual products.

Some months since (see before, p. 421) considerable interest was excited by the announcement that Dr. Freire, of Rio Janeiro, had detected the presence of the organism causing yellow fever in soil taken from graves of persons who had died of the fever, and that he had succeeded in communicating the disease to rabbits and guinea pigs by the injection of liquid in which the organisms had been cultivated. But in an interesting communication since forwarded to the Government from the island of Barbados an account is given of the results of a number of control experiments made by the Rev. J. H. S. Moxly, Chaplain to the Forces, who has had a medical education, and Mr. J. B. Harrison, Island Professor of Chemistry, which fail to confirm those reported by Dr. Freire in the least degree. Messrs. Moxly and Harrison's experiments were made with soil taken from the graves of persons who died of yellow fever in the epidemic of 1881 and at other times, from graves other than those of yellow fever patients, and from open fields on which no manure had been used. Previously sterilized chicken soup impregnated with any of these moulds and kept at the ordinary temperature usually became turbid in a few hours, and by the second day had assumed a bright yellow colour, especially at the top, the colour being most strongly manifested in the case of a soil from a yellow fever grave and one from an open field. The exceptions were liquids in which soil was sown taken from yellow fever graves where a layer of lime had been placed above the coffin. These coloured liquids, although crowded with bacteria, were injected into guinea pigs without producing any symptoms that could be referred to yellow fever, or, as a rule, any inconvenience. Similar negative results, so far as symptoms of yellow fever were concerned, were observed when decomposed matter was used from the coffin of a person who had died of the disease, the guinea pigs in such cases apparently dying of septicæmia, no bacteria being detected in the blood, the corpuscles of which were considerably disintegrated, and no albumen in the urine, though this is an invariable accompaniment of yellow fever in the human subject. When the "moulds" were cultivated at 98·5° F. the liquid acted much more virulently; but the symptoms were still those of blood-poisoning and not of yellow fever, the absence of bacteria from the bodies immediately after death being remarkable. Summing up their results, Messrs. Moxly and Harrison say that they can discover no difference between a micrococcus from a grave and one from a garden, and they add, with somewhat more than a *soupçon* of satire, that had Dr. Freire been a tyro with the microscope they would have been inclined to refer some of his observations to mismanagement of that instrument, but, seeing that the *Chemical News* looks upon him as possibly one of the greatest benefactors of the human race, and the *Lancet* anticipates with pleasure the continuation of the account of his experiments, they can only confess themselves "completely puzzled."

It is also noteworthy that Dr. Klein has failed to obtain results confirmatory of M. Pasteur's celebrated experience in respect to anthrax in sheep. According to M. Pasteur it is possible to obtain by cultivation of the *Bacillus anthracis* at a temperature of 42° to 43° C. a liquid that possesses the character of a vaccine against the disease. But Dr. Klein's experience with his artificial cultivations when injected into sheep was similar to a former trial upon rodents; either he obtained no result whatever from inoculation, or else the animal was killed by it, as it would be by inoculation with the original anthrax bacillus. Dr. Klein, therefore, obtained a supply of M. Pasteur's "vaccin charbonneux," as sold by the agent in Paris. This is described as consisting of two liquids,—"premier vaccin," and "deuxième vaccin," —which are to be used in succession, the two inoculations being alleged to confer on the animals immunity from charbon. But no such results were obtained by Dr. Klein: the "premier vaccin" in some cases caused death by anthrax, and the "deuxième vaccin" was even more fatal; whilst animals that survived the two inoculations died of typical anthrax when subsequently inoculated with cultivations of *Bacillus anthracis*, showing that M. Pasteur's "vaccin" had not conferred upon them the desired immunity. Without, therefore, wishing to throw doubt on the accuracy of M. Pasteur's statement as to the results obtained in France by the vaccination of sheep with anthrax vaccine, Dr. Klein questions his statements as to the universal applicability of his results, whilst it is suggested by Dr. Buchanan that probably the conditions for the manufacture of an attenuated anthrax virus are numerous, and not all understood by M. Pasteur himself. One observation made by Dr. Klein seems to indicate a behaviour of the anthrax virus similar to that with which the small-pox virus is generally credited, and which M. Pasteur has recently attributed to the virus of hydrophobia, in undergoing an attenuating modification in the body of particular animals.

It was found that the blood of a mouse that had died from anthrax, although it affected constitutionally a sheep vaccinated with it, did not produce a fatal effect, whilst the sheep became insusceptible to further inoculation with virulent material. Dr. Klein also differs from M. Pasteur as to the anthrax bacillus being capable of forming spores in the body of a dead animal and so becoming a source of danger, through the medium of earthworms, to sheep grazing in the neighbourhood.

A new reagent showing the presence of sodium and sodium salts is described by Dr. Hager (*Pharm. Central.*, June 19, p. 291), which, though subject to several limitations as to its applicability, would seem to give more satisfactory qualitative indications than the flame test in such cases as the examination of potassium carbonate or hydrate. It consists in a solution of potassio-stannous chloride, made by dissolving five parts of crystals of chloride of tin in ten parts of distilled water and adding sufficient potash solution, sp. gr. 1·145, to render it nearly, but not quite, clear; after standing an hour five parts more of potash solution and fifteen of water are added, the solution is again allowed to stand for some hours and then filtered. The solution to be examined, if acid, should be made faintly alkaline with pure potash solution, or if decidedly alkaline, neutralized with hydrochloric acid, and any salts of the earth metals should be separated by pure potassium carbonate. Boric acid also interferes with the reaction and a solution containing sodium borate requires to be mixed with potassium chloride or sulphate before adding the tin reagent. In the presence of any of the salts of sodium the reagent gives, after two or three minutes, a white precipitate or turbidity, even with only minute traces, a fact that should be remembered in preparing it, as caustic potash is seldom quite free from soda. Lithium and ammonium salts seem to behave towards this reagent similarly to sodium salts, except that the reaction with lithium is not influenced by the presence of a borate. As alcohol in the proportion of 8 per cent. also gives a white turbidity with potassio-stannous chloride its presence would require to be excluded.

Herr Sturcke has been engaged in an investigation of the constituents of carnauba wax, which, notwithstanding its growing importance, had previously been only partially examined. He reports (*Lieb. Annalen*, ccxxiii., 283) that he has recognized the presence in carnauba wax of the following bodies: (1) a crystalline paraffin-like hydrocarbon, melting at 59° to 59·5° C.; (2) an alcohol, represented by the formula $C_{26}H_{53}.CH_2OH$, and melting at 76° C.; (3) myricyl alcohol ($C_{29}H_{59}.CH_2OH$) melting at 85·5°, from which melissinic acid ($C_{29}H_{59}.COOH$) was prepared; (4) a bibasic acid, $C_{23}H_{46}(CH_2OH)_2$, melting at 103·5° to 103·8° C., and yielding the acid $C_{23}H_{46}(C_2OH)_2$, melting at 102·5° C.; (5) an acid ($C_{23}H_{47}.COOH$), melting at 72·5° C., and isomeric with lignocerinic acid; (6) an acid ($C_{26}H_{53}COOH$), melting at 79° C., identical or isomeric with cerotinic acid; and (7) an acid ($C_{19}H_{38}.CH_2OH.COOH$) melting at 103·5° C.

M. Naudin reports (*Bull. Soc. Chim.*, xli., 483) that he has separated from chamomile flowers two crystallizable bodies, one of which he has closely examined. A mixture of the two bodies was obtained by exhaustion of the flowers with light petroleum spirit and they were separated by repeated recrystallization from absolute alcohol. The compound insoluble in cold alcohol is soluble in hot alcohol and also in ether, petroleum, carbon bisulphide and chloroform, but is insoluble in water. It crystallizes in delicate microscopic needles, melting at a temperature of 63°—64° C. M. Naudin proposes to name this compound "anthemen." Upon analysis it gave results corresponding with the formula $C_{16}H_{36}$. Anthemen does appear to yield a bromine addition-product; it resists the action of strong sulphuric acid, but is slowly attacked when heated with nitric or chromic acid, with the formation of acids of the fatty series, in which property it resembles a hydrocarbon discovered by Schutzenberger in Caucasian petroleum.

The gum of a species of *Grevillea* acclimatized in Algeria has recently been examined by M. G. Fleury (*Journ. de Pharm.*, p. 479). The gum is of a yellowish or reddish brown colour, and horny consistence. In water it swells, diffuses slowly, and produces a white emulsion of a very persistent character, which easily passes through the filter. It is found by M. Fleury to consist of a gum approaching in character that of gum arabic, and a fluid reddish transparent resin without odour soluble in alcohol. This resin is also soluble in alkalies, in methylic alcohol and bisulphide of carbon; it possesses feebly acid properties and forms about 5 to 6 per cent. of the gum. The separated gum does not actually dissolve in water, but if a little potash, lime, or carbonate of potash be added to it when swelled up by water, solution takes place immediately, the solution becoming gelatinous upon the addition of a ferric salt. An alkaline solution becomes darker and more viscous if exposed to the air.

The poisonous coating of some arrows brought home by the Riebeck expedition to the east coast of Africa and the Soudan has been submitted to an examination by Professor Harnack. He reports (*Arch. exp. Path. u. Pharm.*, xviii., 1) that it resembles in appearance a vegetable extract and that he has separated from it a glucosidal non-nitrogenous substance, resembling digitalin closely in its physiological action and its products of chemical decomposition. Traces were also found of a basic substance, which appeared, however, to have no characteristic physiological action. Nothing is known respecting the source from which this poison had been derived.

Referring to the opinion recently expressed by Dr. Schunck that chlorophyll is a glucoside (see before, p. 602), Dr. A. B. Griffiths recalls his observation of the presence of crystals of ferrous sulphate in proximity to the chlorophyll granules in certain plants, and suggests that probably iron enters into the constitution of green chlorophyll, and that perhaps chlorophyll may consist of a complex molecule of iron and this glucoside (*Chem. News*, May 30, p. 237). He points out that no green chlorophyll is produced in plants growing in soils or other media free from iron, and explains the value of ferrous sulphate as manure by saying that the iron most probably acts as food for the chlorophyll granules, and the sulphur as food for the protoplasm of the cells, etc.

Muscarine, the heart paralysing alkaloid of the fly agaric, the nitrate of which is now used to some extent in medicine as a sudorific when subcutaneously injected, can be prepared artificially by the oxidation of neurine, from which it differs in containing one more atom of oxygen. In investigating its constitution with a view to its more advantageous preparation, Herr Berleinerblaue availed himself of Herr Schmiedeberg's conclusion that it is a trimethylamine base, and inferred that by heating monochloracetal together with trimethylamine in a closed tube to 100°—120° C. a product would be obtained capable of yielding muscarine by suitable saponification (*Berichte*, xvii., 1139). The reaction went on as expected and a compound was formed that appeared to correspond in composition with a neutral ethyl ether of natural muscarine, together with another base that contained a molecule of water of hydration less. Both bases appeared to correspond qualitatively with muscarine in their physiological action, but that of the ether was the weaker.

A correspondent of the *Pharmaceutische Centralhalle* (xxv., 281) recommends the use of water that has been redistilled in the preparation of solutions of morphine for subcutaneous injection and the use of a salt as free from contamination with dust particles as possible. Ordinarily he dissolves 10 grams of morphine hydrochlorate in 200 c.c. of redistilled water at a temperature not exceeding 35° C., the solution only being submitted to filtration if any particles can be detected swimming in it with the naked eye. Such a solution he has found to keep unaltered during a month.

In reply to a question as to the best solution for an iodoform "spray," Mr. Alfred Leach writes (*Lancet*, May 31, p. 1012) that he finds it convenient to use a mixture of ethereal and chloroform solutions. The proportions he uses are—ethere salolution of iodoform, one drachm; chloroformic solution of iodoform, one scruple; fresh tincture of senega, a drachm and a half; water to two ounces. The addition of a little ol. pini sylvestris before the water is found to mask the odour of the iodoform considerably. The mixture is said to be of a straw colour, and to hold iodoform in suspension in a minute state of division.

According to Dr. Biel (*Pharm. Zeit. Russl.*, xxiii., 301) the increased consumption of iodoform in medicine has led to considerable sophistication. He recommends that it should be tested by shaking a small quantity with water, and filtering, when the filtrate should be colourless. If this filtrate be treated with solution of potassium cyanide it undergoes no change if the iodoform used was pure, but if it contained only a trace of picric acid the liquor within ten minutes shows the red-brown colour of isopurpuric acid.

In the *British Medical Journal* (June 7, p. 1126), a correspondent points out that the use of strychnia in medicine causes a distaste for tobacco and affords an easy means of breaking off the habit of smoking to those who are desirous of doing so. He found that, both when taking tincture of nux vomica and Easton's syrup, he no longer cared for his pipe, and after a time took a positive dislike to it. This may perhaps be explained on the principle that strychnia is a physiological antidote to tobacco, and that smoking would therefore cease to give its soothing effect when the system was under the influence of strychnia. If this be correct, a physiological antidote to the effects of alcohol would be worth seeking, on the chance of it producing an analogous result.

Some experiments made by Dr. Queirolo with kairin in the medical clinic at Genoa are reported (*Archiv*, xi., 425) to have shown that when this antipyretic is administered subcutaneously a greater fall of temperature is produced, which commences more rapidly and lasts longer than that following when it is taken by the mouth; whilst these effects are obtained with smaller and less frequent doses. The hypodermic injection of kairin is said not to produce any general disturbance or local symptoms, apart from a slight smarting at the point of puncture, which soon passes away. Injections were used containing 10 to 50 centigrams of kairin to each gram of distilled water, brought to a clear solution by the aid of heat and used while still at a temperature between 30° and 35° C.

Another synthetically prepared alkaloid is being put forward as an antipyretic under the name of "antipyrin," concerning the chemical constitution of which nothing has yet been published beyond the statement that it contains oxygen. It is the work of Dr. Knorr, of Munich, and is described s forming a white crystalline powder, freely soluble in water, and having only a very faint taste that can be easily masked if desired (*Pharm. Post*, June 7, p. 513). It has been very favourably reported upon by Professor Filehne, who states that he found it to reduce the temperature in cases of fever very considerably, without producing objectionable symptoms, and that its effects were very prolonged. It was given to adults in two gram doses repeated two or three times at intervals of an hour.

Abrus precatorius still seems to be attracting some attention and is to form one of the subjects for the debate on Indian drugs at the meeting of the British Medical Association at Belfast. In the *Journal de Pharmacie* (June, p. 468), M. Patein gives an account of an examination of the testa of these seeds. He finds them to contain a large proportion of carbonate of lime and rather more iron than hæmoglobin. The colouring matter is soluble in alcohol and contains, so far as has been ascertained, a salt of iron. It is thrown down completely by subacetate of lead as a greenish precipitate. It is also turned green by alkalies and is reddened again by acids.

Reasoning from the known fact that when an infusion of jequerity seeds is applied to what are known as "granular lids" it sets up a specific ophthalmia of a croupous nature, which destroys the granulations and leaves the surface in a condition favourable for healing, Dr. Shoemaker was led to the deduction that the remedy might be applicable to other morbid processes consisting in exuberant granulations and proliferating cell growths, and showing a tendency to a slowly degenerating condition. In a paper read before the Pennsylvania Medical Society (*Med. Bul.*, May 16) he reports that he first tried it in lupoid conditions, epithelioma, and sloughing ulcers, but found the weak infusion used in ophthalmic practice of little avail, though when he used a stronger "emulsio-infusion," a specific inflammation was set up, which occasionally, when applied over extensive surfaces on sensitive patients, assumed alarming proportions. The products of the inflammation, however, formed an immense crust, under the protection of which the constructive process rapidly developed, leaving a new and healthier surface when it was removed, so that by repetition of the application cures were speedily effected. Dr. Shoemaker therefore thinks jequerity will prove to be a most powerful agent in certain affections of the skin, though only to be used with due caution.

In severe cases of small pox, Dr. Pioch recommends (*Archiv*, xi., 425) the painting of the entire body with a mixture of 30 grams of tincture of iodine, 60 grams of glycerine and 25 centigrams of potassium iodide, the solution being applied every six hours with a broad brush. The treatment should begin on the fifth or sixth day of the eruption and last until the eleventh or twelfth day, the subsidence of the eruption being the indication for its cessation. A further advantage of this treatment is said to be the avoidance of pock-marks.

Dr. R. N. Wolfenden directs attention (*Practitioner*, p. 431) to the use of hydrobromate of conia in epilepsy. The dose given by him is ¼ to 1½ grain, according to age, and the results obtained appear to be such as would warrant further trial.

Signor Silvio Plevani (*Lancet*, June 7, p. 1042) has suggested among other economic antiseptic dressings the preparation of absorbent tow, which is effected in the following manner:—The tow is boiled for some time in a lye made of wood ashes or in a 10 per cent. solution of carbonate of sodium and then washed repeatedly in water. When thus deprived of greasy and resinous matter it is immersed in a 10 per cent. solution of chloride of lime and kept in it for some hours with an occasional stirring until it becomes perfectly white. It is then washed thoroughly, dried and carded.

The time for hay fever to be prevalent is now rapidly approaching, and those who suffer from it will doubtless only be too glad to learn of any successful method of treatment. Dr. W. T. Phillips, of Andover, recommends belladonna, which he found successful last year (*Br. Med. Journ.*, July 14, 1883). In the same journal (June 7, p. 1090) he now gives the dose as 1¼ minim of the succus every hour till relieved (30 min. to 3 ozs. of water). For coryza, Dr. G. E. Dobson recommends (*Lancet*, May 31, p. 978) the inhalation of the vapour of camphor and steam, the vapour being made to come in contact with the outer surface of the face surrounding the nose by means of a paper cone placed with the narrow end downwards in a vessel containing hot water and a drachm of coarsely powdered or shredded camphor. If this is continued ten or twenty minutes at a time, and repeated three or four times in as many hours, a cure is usually effected.

A new diuretic is mentioned in the *Therapeutic Gazette*, for May (p. 208), by Dr. U. S. Newlon, of Oswego, who has made some experiments with a cruciferous plant, *Vesicaria gracilis*, which grows west of the Mississippi, and finds that it is a stimulating diuretic of considerable power. Its virtues are best extracted by alcohol or acetic acid.

Dr. Campardon, in the *Bull. Gén. de Thérapeutique*, speaks highly of the use of *Lythrum Salicaria* in acute or chronic inflammations of the gastrointestinal mucous membrane. Its properties appear to be due to tannin and mucilage. An excessive dose, such as 10 to 12 grams per day, produces gastric disturbance. The application of the powder and infusion has been found of service in the treatment of varicose ulcers. The infusion is made of the strength of 30 parts of leaves and stalks to 1000 of water. Of the powder, the dose is 1 gram in a wafer as a dose three times a day (*Therap. Gazette*, p. 238).

The fruit of *Sizygium jambolanum*, an East Indian plant belonging to the natural order Myrtaceæ, has recently been somewhat in demand on the Continent for use in the treatment of diabetes. M. Banatrala (*Répertoire de Pharmacie*, p. 169) has found, in three cases in which he has tried it, that its use led to a diminution in the amount of urine secreted and that it caused the disappearance of the sugar. These results were manifested in forty-eight hours after taking the medicine. During the time that the patients were submitted to the action of the drug they could take amylaceous food with impunity. The astringent rind of the fruit appears to be the active part.

In the *Journal de Pharmacie* for this month (p. 456) Professor H. Baillon describes a Malagasy plant called "hazigne," the fruits of which yield an oil, and the stem a resin, which are used by the natives as a remedy in certain skin diseases, such as leprosy, the itch, and ulcers. The oil obtained from the seeds is also used as food and for lamps The hazigne is a handsome tree belonging to the Guttiferæ, and is named *Symphonia fasciculata*. The fruit is known to the natives by the name of "voa-souvouara." Some of the seeds are now being submitted to chemical analysis by Messrs. N. J. Regnaud and Villejean, and the results will be published in a future number of the *Journal de Pharmacie.*

In the *Practitioner* (p. 435) it is pointed out that the *Pois d'Achery*, a sort of kidney bean (*Phaseolus limatus*, L.), cultivated in the Mauritius and used there as an occasional article of diet by the Creoles, exists in the form of two varieties: the one white, which is generally esteemed wholesome, and the other very prettily variegated, which is regarded as poisonous. The poisonous character of the latter is due, according to Drs. Davidson and Stevenson, to hydrocyanic acid, which is formed when the beans are macerated in water by a similar process to that by which it is produced in certain plants of the Rosaceæ, such as the almond and cherry laurel. The reason why two varieties of a plant which cannot be distinguished from each other by any definite botanical characters should produce different chemical compounds is a most interesting problem, and seems to deserve further investigation.

A Mexican plant, by name "palillo," which appears to be *Croton morifolius*, has recently been the subject of experiment in France, by Messrs Duges and Armendaris (*Bull. Soc. Bot.*, [2], v., p. 233). Two or three drops of the oil contained in the seeds act like a moderate dose of castor oil. The natives of Mexico use the leaves of the plant in the form of infusion as a remedy for gastralgia and atony of stomach. The tincture of the leaves is said by the above-named experimentalists to give excellent results in neuralgia, especially when occurring in the face, either when used as liniment, or dropped into the ears, or taken in the dose of 10 or 15 drops in orange-flower water.

At the last meeting of the New Jersey Pharmaceutical Association (*Amer. Journ. Pharm.*, June, p. 344) Professor Maisch stated that he had recently received from California some "tubers of the parent plant of the cultivated potato." The plant had been discovered by Professor Lemmon, in the Huachuca mountains, Arizona, at an elevation of nine thousand feet, and had been named *Solanum tuberosum*, var. *boreale*, by Professor Asa Gray. The tubers, which had sprouted to such an extent that they had to be planted in order to save them, are described as of two varieties, one white and the other red, but both quite small, being only about half an inch or little more in length.

An interesting paper on the "Existence and Use of Manganese in Animals and Plants" is given in *Comptes Rendus* (p. 1418), by M. E. Maumené. He points out that it is constantly excreted by animals, and therefore does not appear to be necessary to life. On the other hand, certain plants, such as tea, coffee and tobacco, require an abundance, and the want of success in their cultivation may be attributed without doubt to the absence or insufficient quantity of this metal in the soil in which they are planted.

In the *Gardeners' Chronicle* (June 14, p. 777), an illustration is given of a curious malformed fuchsia flower in which two green leaves proceed from outside the middle of the ovary, one of the leaves having a single stamen in its axil, and the other two stamens in its axil, the filaments of which are united half way.

At a recent meeting of the Royal Horticultural Society, a wallflower was exhibited which had grown through the pith of a black currant stem. In this case there was no true epidermis on the stem, which was of two years' growth, and the pith was destroyed or partly converted into cork (*Gard. Chron.*, p. 782).

Science Gossip for this month gives an illustrated paper on the Alpine gentians, the descriptions including the species which yield the gentian root of commerce, *G. lutea*, *G. purpurea*, *G. pannonica* and *G. punctata*.

Those who take an interest in the cause of variation of species in plants will find an interesting article in the *Journal of Botany*, on "Euphrasia officinalis," a species which is very polymorphic. The plant is proterogynous, but has also provision for at least two modes of self-fertilization in case cross-fertilization is not effected, the one in the larger-flowered form by the lengthening of the corolla tube so that the stamens are brought in contact with the stigma, and the other in the smaller-flowered forms by the curving downwards of the upper portion of the style. No less than eight groups, each containing several forms, are enumerated by the author, Mr. F. Townsend. In the some number of this journal a very useful list is given of the new phanerogamic plants published in periodicals during the year 1883, with references to each, the whole being arranged alphabetically. Literature of this kind is so scattered, that the list is sure to prove most useful and will doubtless help to diminish the evils arising from the multiplication of botanical names.

Dr. P. Calvo (*Journal of the British Dental Association*, p. 373) gives as the results of experiments during the last three years a remedy for lessening the sensibility of dentine of decayed teeth which does not injure the vitality of the pulp. This he has found in quicklime. By carefully drying the cavities of the teeth before inserting the powdered lime an undue rise of temperature is avoided, in consequence of the hydration taking place slowly and but little heat being developed. Lime appears to have the advantage over the more soluble alkalies of coagulating the albumen of the immediate surface and thus limiting its caustic action.

At a recent meeting of the Physiological Society of Berlin, Professor Busch (*Nature*, June 5, p. 140) made some interesting observations on caries of the teeth. He mentioned that it has been observed in none of the lower animals, and appears to be peculiar to man. It is not, however, characteristic of civilized races, but has been observed in skulls of prehistoric time. Some races are more disposed to it than others, the Celtic, Arabian and Polish races appearing to possess a relative immunity. Certain families, however, are predisposed to it. This is manifest in the undulating character of the enamel, teeth with smooth enamel having much greater power of resistance. In strong teeth the dentine tubes run regularly side by side close to each other, but in those disposed to caries the dentine tubes branch and surround cellular bodies or small air vesicles. No pain occurs in the course of caries until the pulp of the tooth is reached.

At a recent meeting of the King's County Pharmaceutical Society, Mr. Stevens reported the results of an experiment to determine the loss by volatilization of camphor when exposed to the air. A fresh block of hard camphor was selected, the corners were sharpened and the weight was ascertained to be 2606 grains. It was placed on the 26th of April on one edge in a situation open to the air, but not subject to radiant heat, direct sunlight or currents of air. The accumulated dust was occasionally lightly blown off with the breath, but the block was not dusted or rubbed. On the 13th of May, seventeen days afterwards, the block weighed 2104 grains, showing a loss of 509 grains (over 19 per cent.), or an average daily loss of 29½ grains. In length the block had lost half an inch.

THE ECONOMIC APPLICATIONS OF SEAWEED.*

BY EDWARD C. C. STANFORD, F.C.S.

(*Concluded from page* 1029.)

We now come to the treatment of the residual weed. If the long fronds of the *Laminaria stenophylla* be observed after exposure to rain, a tumid appearance will be noticed, and sacs of fluid are formed from the endosmosis of the water through the membrane, dissolving a peculiar glutinous principle. If the sacs be cut, a neutral glairy colourless fluid escapes. It may often be seen partially evaporated on the frond as a colourless jelly. This substance, which is then insoluble in water, is the remarkable body to which I have given the name of algin. The natural liquid itself is miscible with water, but coagulated by alcohol and by mineral acids. It contains calcium, magnesium, and sodium, in combination with a new acid which I call alginic acid. When this natural liquid is evaporated to dryness, it becomes insoluble in water, but it is very soluble in alkalies. This new substance is so abundant in the plant that, on maceration for twenty-four hours in sodium carbonate in the cold, the plant is completely disintegrated. The mass thus obtained is a glutinous mass of great viscosity, and difficult to deal with on that account. It consists of the cellulose of the plant mixed with sodium alginate. The cells are so small that they pass through many filters, but by cautiously heating it, the mass can be filtered through a rough linen filter bag, the cellulose being left behind, and after the algin is removed, this is easily pressed.

The solution contains dextrine and other extractive matter, and it is then precipitated by hydrochloric or sulphuric acid; the alginic acid precipitates in light grey albuminous flocks, and is easily washed and pressed, in an ordinary wooden screw press. A filter press, made for me by Messrs. Johnson and Company, answers perfectly well for this operation, but not so well for the preceding. It forms a compact cake, resembling new cheese, and has only to be stored in an ordinary cool

* Read before the Applied Chemistry and Physics Section of the Society of Arts. Reprinted from the Journal.

drying room, where it can be kept any length of time. If desired, by adding a little b'each during the precipitation, it can be obtained perfectly white. The algin can be sent out in this state, it is only necessary to dissolve it in sodium carbonate in the cold for use. If, however, it be sent out as sodium alginate, it must be dissolved to saturation in sodium carbonate; the carbonic acid is disengaged, and sodium alginate is formed. If potassium or ammonium carbonate be used, the alginates of potassium or ammonium are formed, which are similar to the soda salt. The bicarbonates of these alkalies may also be used; but the caustic alkalies are not such good solvents.

The sodium alginate forms a thick solution at 2 per cent., it cannot be made above 5 per cent., and will not pour at that strength. Its viscosity is extraordinary. It was compared with well-boiled wheat starch, and with gum arabic in an ordinary viscometer tube; the strengths employed were as follows; it was found impossible to make the algin run at all over the strength employed:—

			Seconds.
Gum arabic solution,	25 per cent.	took	75 = 1 in 3
Wheat starch	1·5 ,,	,,	25 = 1 in 8
Algin	1·25 ,,	,,	140 = 1 in 112

So that the algin has fourteen times the viscosity of starch, and thirty-seven times that of gum arabic.

I append analyses of two samples of commercial sodium alginate of average composition:—

	No. 1.		No. 2.	
Water	17·13		19·30	
Organic matter	59·97		58·125	
Carbonate soda	18·32	P.C. ash 22·90	17·78	P.C. ash 22·575
Neutral salts	2·98		2·77	
Insoluble ash	1·60		2·025	
	100·00		100·00	
Dry algin	67·58		65·50	
Soda (Na_2O)	10·71		10·40	
Per cent. of Na_2O	15·85		15·87	

Showing that, excluding the water, salts, and ash, the composition is uniform.

The solution may be alkaline, or neutral, or acid, according to the degree of saturation; if alkaline, it may be made distinctly acid by the addition of hydrochloric acid, but any excess at once coagulates it; a 2 per cent. solution becomes semi-solid on this addition.

The evaporation is effected in a similar manner to that of gelatine, in thin layers on trays or slate shelves, in a drying room with a current of air, or on revolving cylinders heated internally by steam; high temperature must be avoided. The solution keeps well. Thus obtained, the sodium alginate presents the form of thin, almost colourless, sheets, resembling gelatine but very flexible. It has several remarkable properties which distinguish it from all other known substances.

Algin, or sodium alginate in solution is precipitated or coagulated by alcohol, ethylic and methylic, acetone, and collodion (but not by ether), by hydrochloric, sulphoindigotic, nitric, sulphuric, sulphurous, phosphoric, citric, tartaric, lactic, oxalic, and picric acids; salts of cobalt, copper, platinum, nickel, silver, bismuth, antimony, zinc, cadmium, aluminium, chromium, uranium, barium, calcium, strontium, and tin chloride and bichloride; mercury pernitrate and protonitrate; iron sulphate (white), and iron perchloride (brown); lead acetate, and basic acetate; lime water, and baryta water.

The solution is not precipitated nor coagulated by alkalies and salts of alkalies, including lithium, alkaline silicates, potassium bichromate (not coagulated by boiling), and chromate; sodium stannate, succinate, biborate and tungstate; magnesium and manganese salts, starch, glycerine, ether, cane sugar, amylic alcohol, boracic acid, acetic, carbolic, tannic, butyric, benzoic, gallic, pyrogallic, arsenious and succinic acids; potassium ferrocyanide, mercury iodide, ferricyanide, and permanganate; bromine, iodine and chlorine water; molybdate of ammonia, tartar emetic and peroxide hydrogen. It does not precipitate the ordinary alkaloids.

It is distinguished from albumen, which it most resembles, by not coagulating on heating, and from gelose by not gelatizing on cooling, by containing nitrogen, and by dissolving in weak alkaline solution, and being insoluble in boiling water.

From gelatine, by giving no reaction with tannin; from starch, by giving no colour with iodine; from dextrine, gum arabic, tragacanth, and pectin, by its insolubility in dilute alcohol and dilute mineral acids.

It is remarkable that it precipitates the salts of the alkaline earths, with the exception of magnesium, and also most of the metals, but it gives no precipitate with mercury bichloride nor potassium silicate.

It has a strong rotary power on polarized light. Mr. Tatlock estimated it for me as having a specific rotary power of 86·5° on Laurent's polariscope. This again fixes its position among animal bodies, gelatine and albumen, and not amongst such vegetable products as pectin, which is neutral.

Alginic acid is insoluble in cold water, very slightly in boiling. It is insoluble in alcohol, ether and glycerine. The proportion of soda ash used is one-tenth of the weight of the weed, and the cake of alginic acid obtained is usually about the same weight as the weed. The quantity of dry alginic acid is given below:—

	Laminaria Stem.	Digitata. Frond.
Water	37·04	44·0
Alginic acid	21·00	17·35
Cellulose	28·20	11·00

	Laminaria Stenophylla. Stem.	Frond.	Laminaria Bulbosa.	Fucus vesiculosus.
Water	34·5	40·02	43·28	40·10
Alginic acid	25·7	24·06	17·95	12·22
Cellulose	11·27	15·06	11·15	—

Falkland Islands Giant Algæ.

Nos.	1	2	3	4	5
Alginic acid	11·21	10·09	5·56	7·44	3·34
Cellulose	8·13	7·25	3·50	12·95	9·68

The three gelatinous algæ, already referred to, contain no algin.

The cellulose in the tangle is higher than in any other weed, the outside of the stem being rather fibrous. I append also analyses of the ash of three varieties of cellulose dry, unbleached to show the trace of iodine still retained:—

	Laminaria Digitata.	Laminaria Stenophylla.	Fucus vesiculosus.
Yield of char.	38·36	36·41	44·62
Soluble	11·08	5·27	11·06
Carbon	12·73	14·27	15·93
Ash	14·55	16·87	17·63
Iodine	·12	·06	·05
On air dry plant about	·012	·006	·005

The new process may be tabulated as follows:—

		Per cent.
Extracted by water—		
Salts	20	
Sugar, mucilage, etc.	10	
	—	30
Extracted by sodium carbonate—		
Algin	20	
Dextrine, etc.	10	
	—	30
Cellulose		10
Moisture		30
		—
		100

Of these, I have accounted for the salts, the algin, and the cellulose, leaving the mucilage, dextrine and sugar for further investigation.

It is not necessary to extract the salts first with water, it comes to the same thing to act on the seaweed at once with soda ash, and to recover the salts by evaporation of the solution, after the alginic acid has been precipitated. In this case chloride of calcium or of aluminium may be employed, the alginate of calcium or aluminium being precipitated. With either salt the alginate is thrown down instead of rising to the surface of the liquid, and the cakes are more compact and easily pressed. In addition to the cheapness with which it can be procured in almost any quantity, as a bye-product in alkali works, now all thrown away, the calcium chloride has the advantage of throwing down the sulphates in the salts, and decomposing them into chlorides, so that the salts consist of chlorides of potassium and sodium, which are easily separated, and do not require the tedious and expensive processes necessary in the lixivation of kelp. The same remark applies to aluminium chloride, which can be cheaply obtained by dissolving bauxite in hydrochloric acid. Either salt can be decomposed by hydrochloric acid, and the calcium or aluminium chlorides recovered; or the salts can be decomposed by sodium carbonate. The calcium alginate, when dry, is very like bone, as the dry alginic acid is like horn. The aluminium alginate is soluble in caustic soda, forming a neutral solution, and giving, on evaporation, a substance like algin, but harder and making a stiffer finish; it is also soluble in ammonia, the salt becoming an insoluble varnish on evaporation. The alginates of copper (blue), nickel (green), cobalt (red), chromium (green) and zinc, are all soluble in ammonia, and form beautiful coloured insoluble films on evaporation. So also do the alginates of platinum, uranium (yellow), and cadmium. The latter is exceedingly soluble in ammonia. The alginate of chromium is also soluble in cold water, and it is deposited on boiling the solution, becoming then insoluble.

With bichrome, algin acts as gelatine, the mixture becoming insoluble under the influence of light. The silver alginate darkens very rapidly under exposure to light, and suggests applications in photography. Algin forms a singular compound with shellac, both being soluble in ammonia; it is a tough sheet which can be rendered quite insoluble by passing it through an acid bath.

Commercial Application of Algin, or Sodium Alginate.

For Sizing Fabrics.—A soluble gum of considerable elasticity and flexibility is a great desideratum; so also is a soluble substitute for albumen, which can be easily rendered insoluble and used as a mordant. As a finish, algin has the advantage over starch, that it fills the cloth better, that it is tougher and more elastic, that it is transparent when dry, and that it is not acted upon by acids. It imparts to the goods a thick clothy elastic feeling, without the stiffness imparted by starch. It has the additional advantage, which no other gum possesses, of becoming insoluble in the presence of a dilute acid, which decomposes starch or dextrine. No other gum has anything like the viscosity in solution, and therefore none will go as far in making up the solution or cover such a large surface. Lime-water, salts of calcium, barium, and various metallic salts can be employed for rendering the coating insoluble. If greater stiffness be required, the algin can be mixed with gum arabic, starch, dextrine, gelatine, albumen or glue, in any proportion.

The alginate of alumina, in caustic soda, is a stiff dressing, and in the crude, unbleached state, will be a cheap dressing for dark materials; and in the colourless state for finer fabrics. The ammoniated alginate of alumina can be used to give a glossy surface, which is quite insoluble after drying.

As to its use as a mordant in dyeing, I quote from Mr. John Christie, of J. Orr Ewing and Co., to whom I am indebted for the fine specimens of Turkey red dyeing exhibited, some of which are finished and mordanted with this new substance instead of cow dung:—"There is another application of the alginate of soda that occurred to me might be of some interest, namely, in the fixing of mordants, such as alumina or iron, upon cotton fibre. I find, so far as I have gone with the experiments, very encouraging results. I believe a very large application will be found for the alginate of soda as a dunging substitute. The mordants, when precipitated, seem to have full dyeing power, the results indicating that this substance is capable of taking the place of cow dung, as used in print and dye-works; also as a dunging substitute it will rank with arseniates, phosphate and silicate of soda, and a number of other salts, which are now largely used for the precipitation of mordants previous to the dyeing of cotton fabrics and yarns."

As an Article of Food.—Algin contains—carbon, 44·39; hydrogen, 5·47; nitrogen, 3·77; oxygen, 46·37; or about the same amount of nitrogen found in Dutch cheese. It has a slight pleasant marine taste, easily overcome if objected to, and may form a useful addition to the kitchen for thickening soups and puddings. It appears specially adapted to replace gum arabic in the manufacture of jujubes and lozenges. To make it into jelly, requires addition of gelose or gelatine, or admixture of lemon juice.

It will be useful for some pharmaceutical purposes, as for emulsion of oils, as an excipient for pills, and for fining of spirits.

For Boiler Incrustation.—The sodium alginate has a remarkable effect in resolving and preventing the incrustation of boilers. My friend, Mr. Spiller, who introduced the first, and one of the best fluids for this purpose, first suggested this application. He found it to precipitate the lime in a state in which it could be easily blown off. Further experience has fully corroborated his opinion. The solution is pumped in with the feed water, in the proportion of 1 lb. to every 1000 gallons. Where hard waters are a necessity, the saving of fuel is considerable.

For Covering Boilers.—The seaweed charcoal, in conjunction with algin, is used for this purpose, and has been largely applied under the name of "carbon cement." It is nearly all charcoal, 3 per cent. of the algin being sufficient to make it cohere. Charcoal is known to be the best solid non-conductor of heat, and in this way its application to steam boilers has been made practicable. It forms a cool, light, and efficient covering.

Algic Cellulose.—This substance bleaches easily, and under pressure becomes very hard, and can be turned and polished with facility. It also makes a good paper, tough and transparent, but with no fibre. Alone, or mixed with algin and linseed oil, or shellac, it may be used as a non-conductor of electricity, where a cheap material is required.

Although there is still a small portion of the plant not accounted for, which will, I hope, also soon be worked out, I think enough has been discovered to justify the following conclusions:—

1. The only way to effectually utilize seaweed is to import it in the raw state.

2. By following the wet process, the additional cost is fully made up by the greatly increased amount of iodine and salts obtained from the water solution, leaving two-thirds of the plant for further treatment.

3. That by extracting from this the algin and the cellulose we utilize the whole plant, and obtain two new products of considerable commercial importance.

4. That the process is extremely simple, and requires no extravagant plant; nor do operations on the large scale present any serious practical difficulties.

5. That the new substance, algin, has very remarkable properties, which may find many aplications not yet known, when it can be put on the market.

6. That the demand for such a substance in fixing and mordanting fabrics alone is enormous.

Our annual export of textile manufactures and yarns is valued at £40,000,000, or more than half the value of our total exports; and a large portion of this requires some dressing material to fit it for the market. We import about £200,000 worth of gum arabic, a good deal of which is used for this purpose; and the war in the Soudan is raising its price, and making it scarce.

7. That the supply of raw material is almost unlimited. Seaweed damaged by rain is equally available for the manufacture of algin.

I will only add that I bring forward this process with some confidence, as the result of a quarter of a century's scientific work, and an almost equally long practical experience—an experience gained in a wide and wild school. I am satisfied, whether it may be given to me to carry it out or not to the extent it should be, it will become the process of the near future. It immediately possesses the advantage of obtaining known marketable products of considerable value, and it bids fair to open up a new industry which may become one of large extent, supplying, as it will, new products for which there is an absolute want. On the other hand, the importance of attaching a marketable value to seaweed can scarcely be overrated. No Royal Commission will give the crofters and cottars on the shores of the Hebrides and the West of Ireland anything like the satisfaction that the offer of £1 per ton for all the seaweed they could gather would. In all these places the sea quest might soon become more important than the land question. Moreover, a shipping trade in the raw material itself is a great benefit to the out-lying islands where it is obtained, it necessitates cartage, it tends to the improvement of roads and harbours, it improves communication by bringing steamers, and necessarily brings the people closer to civilization, and the great centres of industry. This is especially the case where the expenditure of every thousand pounds on the raw material means the expenditure of about as much on carriage. I have reason to know that the lairds of all these shores would not be entirely dissatisfied with such a result. We should all share in the satisfaction of knowing that one more waste product had been effectually utilized.

INDIA RUBBER AND GUTTA PERCHA CULTIVATION IN CEYLON.*

India Rubber.† *Ceara.*—In Ceylon a planted area of 977 acres is credited to this kind of rubber, but it has not yet appeared among our exports. Since it has been ascertained that the quality is excellent,‡ cultivators have been endeavouring to discover a means by which the milk can be obtained at a cost sufficiently low to give a return, but without, as yet, encouraging results. The removal of the outer separable bark, as practised in the experiments referred to in my last report, has been objected to on the ground that the bark formed in its stead is of a different character, very hard and inseparable from the green layer a second time. Instruments have therefore been devised for bleeding without such removal. A knife with two parallel blades, which took out a strip of bark, has been modified into one in which the very sharp cutting edges meet to form a V, the basal angle during use being at the cambium. Another invention avoids all cutting, being a double spur-like wheel with sharp but guarded points which puncture the bark without further injury. The milking (one can scarcely call it tapping) has also been practised on trees of various ages and at different intervals and seasons. While it is found that the yield of individual trees varies extremely,§ none of the experimenters is satisfied that the small quantity obtainable by present methods is sufficient to make the cultivation profitable at the existing price of rubber. Mr. Wall, however, who states that hundreds of young trees have been bled *daily* with the "pricker" for some weeks, and that thus a cooly can collect about half a pound of dry rubber per diem, thinks that, if trees will bear this treatment for two hundred and forty days in the year, the cultivation would be remunerative. It appears evident that milking must be repeated at frequent intervals, and (as often already pointed out) the cultivation be conducted on a large scale. Much of the 35,000 acres in private hands in Ceylon, at present growing nothing but *Lantana* and other weeds, is suitable for this hardy plant, which costs nothing to cultivate, affords a substance of a value which is continually increasing, and awaits only the discovery of a process by which the latter can be cheaply and exhaustively extracted.

Castilloa Rubber.—From a single tree at Péradeniya a considerable crop of seedings was raised. The fruits ripened at the end of May; they are little, white, pointed nuts, about half an inch long, covered by a bright orange pulp, and some twenty to thirty are crowded together on the fleshy flattened scaly receptacle, forming collectively what is called a compound fruit: about half of the fruits ripen and contain each a single seed. I have already expressed my opinion as to the suitability of this tree for cultivation by a Forest Department as a source of prospective revenue; and as comparatively few of the plants were disposed of to private persons, I made an endeavour to get plantations of this valuable tree formed at Ratnapura and Kalutara. The plan was sanctioned by the Governor, and I gave the necessary instructions: but after three months' delay it was discovered that the trifling sum necessary could not be provided.

The growth of the largest *Castilloa* tree at Henaratgoda is, at a yard from the ground, 30¼ inches, an increase of 4¼ inches during the year.

Para Rubber.—Nine trees flowered at Henaratgoda in March, and the fruit ripened in August. About two hundred and sixty seedling plants were raised, many of which have been disposed of to persons desirous to try the cultivation. Our largest tree is now 30 inches in circumference, an increase of 4½ inches in the year.

Eighteen plants of another species of Hevea, *H. Spruceana*, were received from Kew in October. This is a native of British Guiana where it is generally known by its Arawack name "Hatie." It has been studied in its native forests by Mr. Jenman, who sent us a plant in 1881, which unfortunately died. Dr. Spruce also collected it on the Amazons. It is closely allied to *H. brasiliensis*, and grows under quite similar conditions. The specimen of the rubber sent home by Mr. Jenman for report appears to have been unfortunately mixed with some impurity which prevented its value being accurately ascertained. The plants have been put out mostly at Henaratgoda, and are doing well.

Some seeds of this species were also kindly sent to the garden by the Manager of the Ceylon Company, Limited, in July, but were quite dead. It is useless to attempt to import seeds of this description from any distance, as they lose their vitality in a few days.

Other Rubber Plants.—Landolphia Petersiana, one of the East African rubbers has flowered during the year, and *L. Kirkii* is now in bud at Henaratgoda. Two plants of *Tabernœmontana crassa* are now doing well. Among seeds received from Mr. L. Wray, of Perak, were some of "Gutta Singret" which appears from leaf specimens, also sent, to be a species of *Chilocarpus*, another climbing apocynaceous genus. Its rubber is not of a good quality, and is chiefly used for adulteration. A few plants were raised and are planted at Henaratgoda.

Gutta Percha.—A valuable series of dried herbarium specimens, of wood, and of the commercial products of the various gutta-producing trees of Perak, has been sent by Mr. L. Wray, jun. (collecting for Sir H. Low), which

* From the Report of the Director of the Royal Botanic Gardens.

† The import of Caoutchouc into Great Britain during 1882 amounted to nearly 20,000,000 pounds.

‡ I am informed that as much as 4s. a pound has been obtained for Ceylon Ceara rubber.

§ This is to be expected; for it should be recollected that the "milk" in plants is quite distinct from their sap, and is contained in special channels. It has no nutritive function, but, like the alkaloids in cinchona, is rather of the nature of an excretion. Its removal, therefore, *per se*, inflicts little or no injury on the plant.

has enabled me to determine with more certainty the species we possess is a living state. He has also sent me a copy of a report to Sir H. Low on the gutta question, which contains some valuable additional matter to that collected at Kew and published in the report of that institution for 1881, pp. 38-47.

I am now satisfied that the identification of "Gutta Sundek" with *Payena* (*Ceratephorus*) *Leerii*, on which doubt has been thrown, is correct. Mr. Wray describes the tree as partial to swampy places near the coast even where the water is salt; the wood is hard and close-grained, and the fruit sweet and eaten by the Malays. There is an inferior variety with a thinner bark known by its longer leaves. Our plants at Henaratgoda have grown quickly; their rate of growth is much more rapid than the species of *Dichopsis*—the largest are over 8 feet high; the tallest at Péradeniya is 6 feet 2 inches.

The young plants of "Gutta Taban putih" grow very slowly. The good dried specimens now sent show this to be distinct from *Dichopsis Gutta*, but I am not able to say to which species of *Dichopsis* they should be referred. This tree is found in the lower hills, 1800 to 2500 feet, and not in the plains; the gutta is a dirty white (whence the name putih = white), coagulates slowly, and does not thoroughly soften even in boiling water. Mr. Wray also distinguishes a small-leaved variety with a longer fruit.

The specimens further confirm our previous knowledge that the best and most frequent sort of gutta percha of commerce, "Gutta Taban merah," is the produce of *Dichopsis Gutta*. Our trees of this are now nine years old, but the tallest is but 9 feet high. According to Mr. Wray, this tree attains 100 to 200 feet in height, with a clean straight trunk of 4 to 5 feet diameter, flanked at the base with large thin buttresses; the bark is $\frac{1}{3}$ to $\frac{1}{2}$ an inch thick, brown-red in colour, and flakes off; the leaves are much narrower on young plants than old ones, the flowers are white, and the seeds yield an oil solid at ordinary temperatures, but used for cooking. The gutta is at first white and cream-like, but becomes pink and ultimately brownish-red ("merah" = red), and this colour is strongly imparted to the water in which it is washed. There is a variety of this species affording a paler gutta called "Gutta Taban sutra" ("sutra" = silk), which is found at a higher elevation (500 to 600 feet).

Other sapotaceous trees affording gutta, of which specimens have been sent by Mr. Wray, are "Gutta Taban simpoo," *Dichopsis Maingayi*, Clarke—the product of which is also sold as "gutta putih"—and "gutta garru," *Bassia Mottleyana*, De Vriese, which gives a white hard sort, only used for mixing with other kinds. He also sends examples of the curious substance called "Gutta Jelutong," used for adulterating gutta percha. It is obtained from a very lofty apocynaceous tree allied to our "Rukattana" (*Alstonia scholaris*),* and recently named *Dyera costulata* by Sir J. Hooker.

The yield of the gutta percha trees seems to be very small—less even than the rubber trees. Thus, from a tree of *D. Gutta*, thought to be over one hundred years old, and over 100 feet high, Mr. Wray succeeded in extracting, by the ordinary native method of felling and ringing the trunk and branches, only 2 lbs. 5 ozs. of clean gutta. Of "Gutta Taban putih," a tree 10 inches in diameter, gave 2 lbs. 11 ozs., and one of *Payena Leerii*, 2 feet 8 inches in circumference, only $6\frac{1}{2}$ ozs. Mr. Wray has satisfied himself that only about $\frac{1}{30}$ part of the gutta percha actually in the bark is extracted by this method, and he believes that by pounding and boiling the bark the whole could be obtained. As the question of the supply of gutta percha is becoming a pressing one, it is to be hoped that experiments on a large scale may confirm this opinion. To quote Sir J. Hooker ('Kew Report,' 1881, p. 38), "the time cannot be far distant when the natural sources of gutta percha will be definitely used up." In view of this contingency it behoves the Governments of those few British colonies—Ceylon being one—in which the trees will grow, to lose no time in establishing plantations, which must in the future become a valuable source of revenue. But in this colony, neither in this case nor in the case of india rubber, can anything be done until a proper forest conservancy is established.

* This appears to yield a somewhat similar substance at Singapore, called Gutta Pulei.

THE VALUATION OF TARTAR EMETIC.*

BY W. B. HART.

The adulteration and consequent lessening of the valuable ingredient in drugs and dye-wares tends to develop methods of analysis, by which the commercial value of them may be rapidly determined, and thus the user and honest manufacturer be protected. Tartar emetic, whose value to the dyer depends solely on the amount of antimony it contains, has of late been lowered in quality, until in some cases it contains only about one-half the amount of metal that a good commercial sample should have. The usual method of estimating the antimony in this salt is by means of a standard solution of iodine, as recommended in most volumetrical analysis manuals. This method gives good results in careful and patient hands, but I find that it can be well replaced by a solution of calcic hypochlorite, or common bleach liquor, of a strength of about 2° Twaddell. The value of the hypochlorite can be found by using a standard solution of sodium arsenite. The sodium arsenite is the usual decinormal solution, made by dissolving 4·95 grams of pure arsenious acid in a solution of sodium carbonate, and when cool diluting to 1 litre. About 25 grams of sodium carbonate are required.

1 c.c. = ·00355 grams of Cl, or ·0061 grams Sb.

The usual potassic iodide and starch paper are needed. The process is conducted as follows:—A weighed portion of the tartar emetic is dissolved, assisted by heat, cooled, and made alkaline with sodium carbonate. A known amount of the calcium hypochlorite solution is added in excess, this being shown by the blue colour which a drop of the liquid gives to the starch paper. The excess of calcium hypochlorite is now found by titrating with the standard sodium arsenite, until the liquid ceases to give the blue colour to the starch paper. The value of the hypochlorite added is found by taking an amount equal to that put to the tartar emetic, or an aliquot portion may be taken, making alkaline as before and titrating with standard arsenite, Penot's method. If an aliquot part is taken, the value of the whole is then to be calculated. The worth of the total hypochlorite added being known, and that of the excess also known, the amount of hypochlorite and therefore chlorine used to oxidize the antimony is thus obtained by difference. This also gives the amount of antimony. The reaction that takes place is as follows:—

$$Sb_2O_3 + 2Cl_2 + 4NaHo = Sb_2O_5 + 4NaCl + 2H_2O$$
$$\therefore 71\,Cl = 122\,Sb.$$

This process is rapid, and, for all practical purposes, accurate, the end of the reaction being sharp, and denoted at once, which with the iodine process is both tardy and tiresome.

The calcic hypochlorite solution, the value of which should be found at least once a day when required, must be kept in a stoppered bottle in a dark place, as it decomposes quickly if exposed to light and air. Even then it will not be of use long, but a fresh solution can easily be made.

The following are the results obtained by this process, along with those obtained by the iodine method, showing comparison:—

* From the *Journal of the Society of Chemical Industry*, May 29, 1884.

	Iodine Process.	Chlorine Process.
No. 1. Mean of 3 trials.	33·41 p. c. Sb	33·29 p. c. Sb
	37·048 „ „	36·944 „ „
No. 2.	36·896 „ „	36·820 „ „
	37·000 „ „	37·020 „ „
Mean	36·981 p. c. Sb	36·928 p. c. Sb

This method might be reduced to a comparative test only.

Let a standard sample of tartar emetic be procured in which the amount of antimony is known. Equal weights of the standard sample and of the sample to be tried are dissolved separately. From a Bink's or glass tap burette is added to the standard sample a solution of bleach liquor until the liquid just blues the aforesaid starch papers. The amount of bleach liquor used is noted. The second sample is treated in the same way. The relation of the antimony in the samples will be in the direct ratio of the volume of bleach liquor taken, and, therefore, in dyeing the amounts to be taken to produce a certain shade will be in the inverse ratio.

Example.—Equal weights of the standard sample (1), and of the second sample (2), were dissolved. No. 1 took 30 volumes of bleach liquor, and No. 2 took 20 volumes; then the ratio of the amount of antimony is as 3 to 2. Therefore, in practical work, for every two parts of the standard sample, three parts of the sample in question must be used and those give the same result.

NOVELTIES IN VARNISHES AND SHOE POLISHES.*

The *Scientific American* translates the following from a German publication called *Neuste Erfahrungen*:—

Reinhardt has devised a method of destroying the stickiness of varnish, which consists in placing the article in a closed vessel or chamber where it can be exposed to the action of ozonized air in motion.

A leather varnish or polish is prepared by Gunther, of Berlin, by mixing a filtered solution of 80 parts of shellac in 15 parts of alcohol, with 3 parts of wax, 2 parts of castor oil, and a sufficient quantity of pigment. The mixture is evaporated in a vacuum to a syrup. The varnish is applied to the leather with a brush moistened with alcohol or with a colourless alcoholic varnish.

Nicolet, of Lyons, prepares boot blacking by dissolving 150 parts of wax and 15 parts of tallow in a mixture of 200 parts of linseed oil, 20 parts of litharge, and 100 parts of molasses, at a temperature of 230° or 250° F. After this 103 parts of lamp-black are added, and when cold it is diluted with 280 parts of spirits of turpentine, and finally is mixed with a solution of 5 parts of gum lac and 2 parts of aniline violet in 35 parts of alcohol.

Hein, in Kaufering, makes another kind of shoe blacking by melting 90 parts of beeswax, or ceresine, 30 parts of spermaceti, and 350 parts of spirits of turpentine, with 20 parts of asphalt varnish, and adds 10 parts of borax, 20 parts of lamp-black, 10 parts of Prussian blue, and 5 parts of nitro-benzol.

Brunner uses 10 parts of bone-black, 10 parts of glucose syrup, 5 parts of sulphuric acid, 20 parts of train-oil, 4 parts of water, and 2 parts (carbonate of) soda. The bone-black and glucose are stirred with the acid in a porcelain vessel until the whole mass is homogeneous and has a shining black surface when at rest. The soda is dissolved in a little water, and boiled with the oil under constant stirring until it forms a thick liquid, and then the other mixture is stirred into it. By varying the proportions of these two mixtures the blacking is made thinner and softer, or harder and firmer. The substances sold as French polish are mostly composed of these ingredients. In this and all other kinds of shoe blacking made with bone-black and sulphuric acid, the precaution must be observed of stirring rapidly and evenly after the acid is added, otherwise lumps will be formed that are difficult to crush, and the blacking will have a granular condition that does not belong to it. Good shoe blacking must always remain soft, and show a smooth, uniform surface when applied to the leather.

* From *Pharmaceutical Record*, June 1, 1884.

BOLIVIAN CINCHONA FORESTS.*

The great progress made in the acclimatization of cinchona trees in India, Ceylon, and elsewhere, has awakened the Governments of countries where the plants are indigenous to the necessity of conserving from reckless destruction, and re-planting denuded forests, so as to be able to keep up the supply of this valuable product.

In Bolivia, since 1878, according to the report of the Netherlands Consul, private individuals and land owners have taken up the question with great earnestness, and at the present time on the banks of the Mapiri, in the department of La Paz, there are over a million of young trees growing.

New plantations have also sprung up in various other localities, either on private ground or that owned by Government. The competition of India and Ceylon in supplying the markets, has had also the effect of inducing more care in collecting and also of revisiting old spots, often with the result of a rich harvest of bark which had been left on partly denuded trunks, and the opening up of new localities. The new shoots springing up from the old stumps have yielded much quill bark, and the root bark of the old stumps has also been utilized.

The re-planting entails very little expense. The Indian tenant on an estate has a house and land from the owner (hacienda) of the estate. For this he binds himself to work for two to four days a week, at from 28 to 36 cents. per day, women and children obtaining 16 to 21 cents. per day. Thus the planting, weeding, etc., during the first two years, is but nominal in expense; after this period the trees may be left to themselves.

On Government land the expense is greater, as after an application being made, the land is put up to public auction, and may fetch a very low or a higher price, according to the bidding. The land secured, contracts are made with natives of the lower class to clear the forest and plant cinchona. The contracts are often sublet to Indians. The young plants are planted from five to six feet apart, with banana trees between, on account of their rapid growth and the shade the latter afford. From March to June, after the wet season is over, is the best time for planting, and the contractor keeps the plantation free from weeds and in good order for twelve months, when it is handed over to the owner. The following is given as the cost of the Mapiri river plantation of an area from sixty or more miles in extent:—

	Dollars.
Ground	1,200
300,000 plants at 0·14 dollars	42,000
Superintendent, buildings, etc. . . .	4,400
Interest	4,800
Total	52,400

Till the plants are above two years of age, they are liable to die from drought or the attacks of ants, and during 1878 many thousands died from these causes. At the end of the fourth year some proprietors begin to collect the quill bark by the method of coppicing.

It is feared by some that should this new venture be successful, it will prove a dangerous rival to the plantations of India, Ceylon and Java, and lower the price of bark considerably.

THE MEDICAL BILL AND PHARMACOPŒIA REVISION.

AT last the Franchise Bill has been fairly disposed of in the House of Commons, and on Tuesday the Government found a favourable opportunity for bringing forward the second reading of the Medical Acts Amendment Bill. This was moved by Mr. MUNDELLA, who said the Bill was a measure of reform which was greatly desired by the medical profession in the public interest, and pointed out that its introduction was not the result of pressure from the outside public, but of an agitation that had been going on among medical men for many years. The principal objects of the Bill were summarized by Mr. MUNDELLA as (1) the reform of the Medical Council by diminishing the number of its members, strengthening their powers, and giving to the medical profession direct representation; (2) the effecting of an approximation to uniformity in the examinations by the establishment in each division of the United Kingdom of a medical board which would regulate the examinations under the control of the Medical Council; and (3) the establishment of a *minimum* threefold qualification—in medicine, surgery and midwifery—which should be required from every person before being placed on the Medical Register. These were described as the main principles of the Bill; but it was admitted that whilst adhering to them there were many details to which the Government was not inclined to pledge itself pedantically and which might be discussed with a view to settlement in Committee. The motion for the second reading was supported by Sir LYON PLAYFAIR, who referred to some of the anomalies arising from the number of licensing boards through which the medical profession could at present be entered, and it received a more qualified advocacy from other members, who evidently were possessed of the views of certain corporations that consider their interests would be injured by the passage of the Bill in its present form. But the force of any opposition was temporarily disarmed by the minister's promise to consider objections when the Bill was in Committee, so that although the sitting came to an end before the Bill was read a second time, there was no indication that any serious objection would be raised to the motion when it next comes before the House, which according to the notices for Thursday would possibly be about the time this Journal goes to press.

One of the details in respect to which Mr. MUNDELLA's invitation will be accepted, and the one which will perhaps be the furthest of all from affecting any principle of the Bill, is that relating to the preparation of the British Pharmacopœia. It is well known to our readers that the Council of the Pharmaceutical Society has decided that the Bill ought not to be allowed to pass through Parliament without an attempt being made to introduce a provision giving to representative pharmacists an official position on the Pharmacopœia Committee. Of course there has been no desire to place any obstacle in the way of the progress of a Bill so much desired by a majority of medical men, and, therefore, no active opposition has been offered to it in the preliminary stages; but the time has now arrived when in the absence of any concession on the part of those in charge of the Bill, the pharmacists of Great Britain, if they wish to remove the disability under which they labour as compared with their *confrères* in any other civilized country, will have to exert themselves to make their wishes known to, and bring their influence to bear upon, the House of Commons. As this may be done most effectually by individuals personally submitting a statement of the facts to the members for their respective constituencies, it will be convenient that we should give here a brief *résumé* of the principal points in the case to be laid before them. It was not until the year 1858 that any provision was made for the compilation of a national pharmacopœia which should have the force of a law throughout the British empire, but by the terms of the Medical Act passed in that year the duty was entrusted to the Medical Council. At that time the pharmaceutical body in Great Britain had so recently emerged from the inchoate condition which had characterized it up to the middle of the present century that no one was surprised that pharmacists did not receive any official recognition in respect to this subject, although it was one in which they were so intimately concerned, and that it was left to the option of the Medical Council either to consult them or to ignore them. We are glad to acknowledge that to a certain extent the Medical Council has followed the former course, but this has been simply as a matter of grace and courtesy. As, however, under the fostering influence of the Pharmaceutical Society the followers of pharmacy have gradually assumed a more worthy position in this country, it has been increasingly felt that the time was at hand when they might reasonably ask for a recognized position in the Committee charged with the revision of future editions of the text-book by the terms of of which they are bound much more stringently than are medical practitioners. As an outcome of this feeling, in 1874, on the motion of Mr. HAMPSON, a resolution was passed by the Council of the Pharmaceutical Society and communicated to the Medical Council, expressing an opinion that it was desirable to associate more practical pharmacists with any Committee which might be appointed for the purpose of preparing any future edition of the British Pharmacopœia and offering to nominate such pharmacists should the Medical Council concur with the suggestion. But the Medical Council contented itself with making the briefest form of acknowledgment of the receipt of the resolution and does not appear to have taken any further notice of it. At any rate another seven years had passed without anything being done, when the present President of the Pharmaceutical Society introduced the subject of Pharmacopœia Revision at the International Pharmaceutical Congress, held in London in 1881, when the reasonableness of the desire thus ignored was strikingly manifested as in the course of the discussion representatives from Germany, France, the United States, Belgium, Russia, Italy, Holland and Denmark rose in succession to say that in their respective countries pharmacists already occupied a position, in respect to the compilation of the national pharmacopœias, more than equal to that asked for so unsuccessfully by the pharmacists of Great Britain and Ireland. The Council of the Pharmaceutical Society, therefore, can hardly be accused of undue urgency or impatience, because when a Medical Bill was introduced into Parliament last year, re-enacting in an unaltered form the existing provisions as to the compilation and publication of the national pharmacopœia, it considered it to be a duty to attempt to urge its views more effectively. A memorial to the Privy Council was, therefore, drawn up and presented, which served as a basis for a large number of petitions afterwards presented to the House of Commons, in which it was asked that a clause should be inserted in the Bill providing for the establishment of a Pharmacopœia Committee consisting of six medical practitioners, to be nominated by the Medical Council, and five pharmaceutical chemists, four to be nominated by the Pharmaceutical Society of Great Britain, amongst whom one should be resident in Scotland, and one by the Pharmaceutical Society of Ireland. It will be remembered, however, that although about four hundred petitions were presented, they were without effect, as the Bill was withdrawn a few days before the end of the session.

The Bill having, however, been re-introduced this session in practically the same form, so far as it applies to this subject, and it having now arrived apparently within a measurable distance of being considered in Committee, the time has come for repeating the work of last year. Within the next few days, we believe, copies of petitions will be sent to Local Secretaries of the Pharmaceutical Society in the provinces and to those other gentlemen who have undertaken to canvass their respective districts and it will be very desirable that they should at once set to work to get them signed as fully as possible and arrange for their presentation by a member of Parliament as soon as ready. In addition to the form of petition issued for signature by chemists and druggists, there will be another for medical practitioners, and, considering that so far as medical opinion has yet been expressed it has been uniformly in accordance with pharmaceutical opinion, it may be hoped that many medical gentlemen will feel at liberty to affix their signatures, especially as there is no longer any danger that by their so doing they will impede the progress of the Bill. We understand that it is also intended to address to every member of Parliament a request to use his influence, and vote if necessary, in the direction of the sense of these petitions, and that in order to enable him to do so intelligently, he will be furnished with a copy of the memorial addressed to the Privy Council, as well as excerpts from the official report of the proceedings at the International Pharmaceutical Congress, consisting of the above-mentioned statements by foreign representatives upon the subject of pharmacopœia revision in their respective countries. It may be convenient to add that a report of the Congress discussion on Pharmacopœia Revision appeared in the number of this Journal for August 6, 1881, and that it was subsequently summarized in the number for April 7, 1883.

The Pharmacopœia Committee of the General Medical Council met on Friday, the 20th inst., to consider the additions and omissions which it is proposed to make in the next edition of the British Pharmacopœia. According to the *Medical Press and Circular* it has been decided that the volume shall be published before the end of the present year.

* * *

Shortly after the last number of this Journal was sent to press, Mr. Mundella, in reply to a question put by Mr. Warton in the House of Commons, stated that the Goverment Bill to regulate the sale of poisons had been drafted, but that before introducing it he was conferring with the Lord Lieutenant of Ireland as to the propriety of extending its provisions to that country.

* * *

The annual meeting in Philadelphia of the Medical Society of the State of Pennsylvania, last month, was made the occasion of the issue of a daily edition of the *Medical Bulletin*, an event that has been only once anticipated in the history of medical journalism.

* * *

Referring to the menthol derived from American oil of peppermint (see before, p. 966), which differs from the ordinary menthol at least in having the odour of peppermint, Professor Maisch suggests that it should be designated "pipmenthol," as even should it prove to be chemically identical a distinctive name would be desirable. Professor Maisch says it occurs sometimes in snow-white acicular crystals and sometimes in white needles with a satiny lustre and forming stellate groups.

We understand that the Silver Medal of the Society of Arts has been awarded to Mr. E. C. C. Stanford in recognition of the merit of his paper on the "Economic Applications of Seaweed."

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, June 19. Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificate was read for the first time:—L. Ehrmann.

During the evening a ballot was held and the Scrutators, Drs. Plimpton and Miller, declared the following gentlemen duly elected Fellows of the Society:—W. Alabaster, H. B. Baker, W. T. Burgess, E. G. B. Barlow, R. D. Courtney, E. J. Caley, M. H. Foye, W. F. Fremersdorff, W. F. Grace, J. Hargreaves, Baron F. Von Mueller, E. L. C. Muspratt, F. Nettlefold, A. G. Page, J. Parr, E. H. Rogers, R. S. Stephens, T. Stormouth, R. C. Tresidder, A. J. Watts, J. S. Wells.

Dr. Gladstone then took the chair while the President communicated the substance of a most important and lengthy paper entitled—

On the Magnetic Rotary Polarization of Chemical Compounds in Relation to their Composition; with Observations on the Preparation and Densities of the Bodies examined. By W. H. Perkin, F.R.S.—In a preliminary note on this subject, read before the Society about two years ago, it was shown that no definite laws could be expected by the ordinary system of comparing the rotary effect of unit lengths of fluid, and that a comparison of molecular lengths (*i.e.* such lengths of fluid that the ray of light in passing through them should in all cases traverse the same number of molecules) must be made if any relationship in the rotary effect of various bodies was to become apparent. It was further shown that the rotation due to these molecular lengths may be calculated from observations made on unit lengths by the formula $\frac{r \cdot Mw}{d}$ where r = rotation observed, Mw the molecular weight and d the density; and that if this number be divided by the number similarly obtained for the standard of comparison (in this case water) the result will be *the molecular coefficient of magnetic rotation*, or more briefly the *molecular rotation.* Examples were then given, calculated from original observations as well as from numbers taken from the papers of Becquerel and De La Rive, fully confirming this view, and plainly showing the existence of definite laws governing the magnetic rotary polarization. These investigations have been continued and the present communication embodies the results of the careful observation of about one hundred and forty substances belonging to the various classes of the fatty series of organic compounds. From these results it is clear that in a strictly homologous series the introduction of each CH_2 is marked by an increase in the molecular rotation. This constant for CH_2 was found (as the means of a large number of closely concordant observations) to be 1·023. Each series has, in addition, it own initial or *series constant*, and it was found that when this initial constant has been once determined for a series by the careful observation of one of its members, the molecular rotation of any other members may be found by the formula Mol. Rot. = s + 1·023.n, where s = the initial or series constant, and n the number of carbon atoms in the molecule. It is found, however, that in speaking of homologous series the first, and in most cases the first two, members of the series must be omitted. This agrees with the results obtained by other investigators, when dealing with other chemical and physical properties, and it appears as if the influence of the hydrocarbon portion of these substances was to a greater or less extent neutralized by that of the extraneous elements, and that the truly homologous series never commences until there are at least three carbon atoms in the nucleus. Again, isomerism plays an important part, and for the above law to hold good it is necessary that the series should be homologous, not only in molecular weight, but also in molecular constitution. Thus, taking as the standard the line formed by the molecular rotation of a series of normal compounds, the numbers obtained for iso and secondary bodies of that series lie above the line, those for tertiary bodies being still higher. In fact, the increase of methyl groups tends to raise the molecular rotation, or, in other words, the more complicated the construction the greater the influence on polarized light. In some cases the influence of isomerism is still more marked, as, for instance, in the case of ethylene and ethylidene compounds, and in fact wherever there are two or more non-hydrocarbon radicals or elements present in the compound. In this case the numbers obtained vary both according to the arrangement of the carbon atoms in the nucleus, and also as to the position of the substituting radicals, whether they are on the same carbon atom, or on neighbouring, or on more distant ones. This is well shown in the case of the ethers of the dibasic acids of the $C_nH_{2n-2}O_4$ series. The acids being solid could not be examined. The normal series appears here to have the formula $COOEt(CH_2)_nCOOEt$, and the first member of the truly homologous series to be succinic or possibly glutaric ether. With the help of the malonic acid derivatives a considerable number of representatives of the lower members of this series were obtained and examined. The four ethers of the formula $C_3H_6(COOEt)_2$ will form good examples of the effect of molecular isomerism in this series. The molecular rotations are ethyl glutarate, 9·403 (calculated from succinate); ethyl pyrotartrate, 9·347; ethyl ethylmalonate, 9·272; and ethyl dimethylmalonate, 9·268. With halogen derivatives of polyvalent radicals these isomeric variations are still more marked, the bromides being especially conspicuous in this respect. Turning to the influence of the successive replacement of hydrogen in a compound—the number of carbon atoms in the nucleus remaining unchanged—by a negative radical, it will at once be seen, from what has been said on the effect of isomerism, that it becomes much more difficult to obtain any *fixed* increment as the cases of possible isomerism are so much increased, and it becomes almost impossible to say which kind of replacement should be considered as constituting the homologous series. This difficulty is much added to by the fact that it is almost impossible to obtain these poly-substituted bodies in sufficient numbers and purity for the determinations, many of the bodies, suitable in other respects, melting at too high a temperature. The abstraction of hydrogen (*i.e.*, the rendering unsaturated) of a compound has a most marked and curious influence on its magnetic rotation, raising it about one unit above the normal line for each diminution of H_2. Thus: propyl alcohol, 3·769; allyl alcohol, 4·683: difference, ·914; and ethylpropylmalonate, 10·367; ethylallylmalonate, 11·281: difference, ·914. Attempts were made to calculate from the results the rotation values of the elements, but it will be seen, on consideration, that as the isomerism of the molecule plays such a leading part in the determination of molecular rotation, the value of the elements must vary according to their position in the molecule and that the most that could be obtained would be values varying between certain limits or constants for certain series. It is believed that this variation of molecular rotation due to molecular isomerism may prove of great use to chemists in helping to determine the constitution of doubtful bodies. The following are the series constants obtained for a large number of different series:—Paraffins, C_nH_{2n+2} ·512; Isoparaffins, ·625; Alcohols, $C_nH_{2n+2}O$ ·700; Iso and Secondary Alcohols, ·845; Oxides, $C_nH_{2n+2}O$ ·642; Iso Oxides, ·932; Aldehydes, $C_nH_{2n}O$ ·264; Iso Aldehydes and Ketones, ·377; Acids, $C_nH_{2n}O_2$ ·393; Iso Acids, ·504; Formic Ethers, ethyl and above, ·495; Acetic Ethers, ethyl and above, ·370; Acetic ethers, Isopositive radicals, ·483; Ethers, methyl, ·273; Ethers, ethyl and above, ·336; Iso ethers, ethyl and above, ·449; Ethers, succinic series, C_nH_{2n-2}; Methyl,

·093; Ethers, succinic series, ethyl, ·196; Ethers, succinic series, iso positive radicals, ·432; Chlorides, $C_nH_{2n}+_1Cl$ 1·988; Iso and Secondary Chlorides, 2·052; Bromides, 3·814; Iso and Secondary Bromides, 3·902; Iodides, 8·006; Iso and Secondary Iodides, 8·092; Ethyl ethers, Oleic series, $C_nH_{2n}-_2O_2$ 1·452. All the observations were made for the D line of the spectrum, a lamp was used in which hydrogen was passed over strongly heated sodium contained in a piece of iron gas barrel, and thus the gas becoming impregnated with sodium vapour burnt at the nozzle and gave a very brilliant monochromatic flame, the size of which could be varied at pleasure. During this research a large number of careful determinations of densities of pure substances were made and attention has already been called (*Chem. News*, xlix., 122) to the relationship which the densities of members of homologous series show to one another and the curves which are formed, both by the densities and coefficients of expansion.

The author exhibited the sodium lamp, the pole pieces of the magnets, the tubes, the modified Sprengel tube for taking the densities, etc.

Professor Ayrton said that although the paper was eminently chemical, he had, as a practical electrician, listened with much interest. It would be of great importance to determine the magnetic value of the field; it would be difficult as the field was not uniform, but it might easily be made uniform. If it were uniform its strength might be measured in terms of Verdet's constant, and we might convert Dr. Perkin's numbers into absolute measurements. This having been done, the apparatus might be used to determine the strength of a current in absolute measure. It would be very portable and very convenient if a suitable liquid were chosen, so many seconds rotation of the D line would indicate so many ampères.

Dr. Glazebrook, some years ago, undertook some researches to determine the magnetorotary power of solutions of certain salts; he had met with two difficulties, the want of a good sodium flame, and the fact that the differences between solutions of varying concentration were so small. A plan somewhat similar to that proposed by Professor Ayrton for determining the strength of a current had been carried out by Lord Rayleigh. The results were not very satisfactory. Bisulphide of carbon was the liquid employed.

After the thanks of the meeting had been given to Dr. Perkin the Society adjourned over the summer vacation to November 6, the following papers, in consequence of the lateness of the hour, being taken as read:—

On the Effect of High Temperatures on Petroleum Hydrocarbons. By Drs. Armstrong and Miller.—In this paper the authors describe the results of their examination of the liquid obtained on compressing oil gas such as is made by passing the vapour of petroleum through highly heated retorts. They point out that their material is in every respect similar to that examined by Faraday in 1825, and in which he discovered benzene. Besides benzene and its homologues, the liquid from oil gas contains hydrocarbons of the ethylene and acetylene series. It is noteworthy that the latter are none of them true homologues of acetylene, as they are incapable of forming metallic compounds analogous to acetylide of copper; they are probably all derivatives of allene, $CH_2.C.CH_2$, the isomer of allylene or methylacetylene. From the fractions boiling below benzene two hydrocarbons of the acetylene series have been isolated, methylallene, $CH_3.CH.C.CH_2$, identical with the crotonylene separated by Caventou from the mixture of hydrocarbons condensed by compression of coal gas, and hexoylene, C_6H_{10}, identical with that described by Schorlemmer. The crystalline tetrabromides of these hydrocarbons have both been obtained in large quantity in a pure condition. As yet it has not been found possible to isolate the intermediate hydrocarbon C_5H_8. The fractions below benzene contain two olefines, amylene and hexylene. A study of their oxidation products shows that both of these are the normal hydrocarbons, the amylene furnishing on oxidation with permanganate normal butyric acid, the hexylene being converted into normal valeric acid; in other words the amylene is normal-propyl-ethylene, the hexylene normal-butyl-ethylene. In conclusion, it is pointed out that this is an extension of the investigation of Thorpe and Young. By heating paraffin under pressure at a comparatively moderate temperature they obtained a mixture, with corresponding olefines of lower (normal) paraffins down to pentane. At the higher temperature of the oil gas retorts, the paraffins are completely converted into olefines, acetylenes, benzenes, etc.; it is not improbable that the benzenes are products in a direct line of the action of heat on the paraffins, and that they are not built up as has been supposed from hydrocarbons of the acetylene series.

On the Decomposition of Terpenes by Heat. By W. A. Tilden.—The following are the conclusions arrived at by the author. When ordinary turpentine oil is exposed to a temperature just short of redness, the greater part of it is transformed in four different ways, viz., into an optically inactive terpene, by polymerization into a colophone, by resolution into cymene and hydrogen, by splitting up into two molecules of a pentine, C_5H_8. These are probably the immediate changes which it undergoes, the small quantities of other hydrocarbons which are simultaneously produced being the result of secondary reactions. The citrenes yield the same pentine as also does terpilene, though less readily. The pentine obtained from the terpenes is identical with isoprene. This pentine is readily polymerized by heat into terpilene. From this easy transformation of $2C_5H_8$ into $C_{10}H_{16}$ and *vice versâ* it appears probable that the molecule of terpilene is composed symmetrically of two halves. The pentine from turpentine, or isoprene as it may now be called, is a lower homologue or isomeric with a lower homologue of heptine from rosin spirit which has been shown by Morris to be probably methyl-propyl-allene. As the pentine is polymerizable by heat or by sulphuric acid into a dipentine, so the heptine may be converted into a diheptine, $C_{14}H_{24}$. It is a liquid boiling 235° to 240°, which appears to possess all the properties of the terpenes. The author intends to examine this compound to ascertain whether it is entitled to rank as a true homologue of turpentine.

A Short Note on the General Law which Governs the Dilatation of Liquids. By P. de Heen.

On the Melting Points of Certain Inorganic Substances. By T. Carnelly and L. T. O'Shea.

On Nitrification. Part III. By R. Warington.

INTERNATIONAL HEALTH EXHIBITION.

Address on the National Value of Public Health.

Delivered at the Inauguration of the Juries, June 17.

BY SIR JAMES PAGET, BART., D.C.L., F.R.S.

I shall speak only of national health. In consideration of his own self a man may be deemed healthy who lives idly, comfortably, and long; who enjoys every day of his life, and satisfies every natural appetite without consequent distress. And when such an one dies of old age, with a timely, uniform, and painless decay of every part, he may be deemed to have been completely healthy; and yet it is possible that he may have enjoyed his own health in the midst of a poor, unhealthy, and unhappy nation, to which he has done no good whatever.

If we could find a nation composed of people such as this man, we might be bound to speak of them as healthy; but we should be right in calling the whole nation utterly unsound, and might safely prophesy its complete stagnation, or its quick decline and fall.

It is not health such as this—idle, selfish, unproductive—that we want to promote either in the individual or in the multitude. Comfortable idleness, such as that of some vagrants and some fine gentlemen, is a despicable result of good health; it is what no thorough man would ever wish for. In view of the national health and welfare, the pattern healthy man is one who lives long and vigorously; who in every part of his life, wherever and whatever it may be, does the largest amount of the best work that he can, and, when he dies, leaves healthy offspring. And we may regard that as the healthiest nation which produces, for the longest time and in proportion to its population, the largest number of such men as this, and which, in proportion to its natural and accumulative resources, can show the largest amount and greatest variety of good work.

Here let me insert, as an interpretation clause, that in all this and what is to follow the word "man" means also "woman," and "he" means also "she;" and that when I speak of work, I mean not only manual or other muscular work, but work of whatever kind that can be regarded as a healthy part of the whole economy of the national life. And I shall take it for granted that a large portion of all national welfare is dependent on the work which the population can constantly be doing; or, if I may so express it, that the greater part of the national wealth is the income from the work which is the outcome from the national health.

It is a common expression that we do not know the value of a thing till we have lost it; and this may be applied to the losses of work which are due to losses of national health. There are very few cases in which these can be estimated with any appearance of accuracy; but I am helped to the best within our present reach by Mr. Sutton, the Actuary to the Registry of Friendly Societies. In his office are the returns, for many years past, of the sickness and mortality among the members of a very large number of these societies; and, among other things, there is recorded the number of days for which each member, when "off work" on account of sickness, receives money from his society. Hence Mr. Sutton can estimate, and this he has been so good as to do for me, the average number of days' sickness and consequent loss of work among several hundred thousands of the workmen and others who are members of these societies. From the entire mass of these returns, he deduces that the average number of days' sickness, per member, per annum, is very nearly one and a half weeks; and this agrees, generally, with the estimates made in other societies by Mr. Neison and others. But the average thus obtained includes the cases of members of all ages, and among them many cases of chronic sickness and inability to work during old age. In order, therefore, to get a better idea of the actual annual loss of work through sickness he has calculated the average annual number of days' sickness of each person during what may be deemed the normal working time of life; that is between fifteen and sixty-five years of age. This he has done among the members of the large group of friendly societies known as the Manchester Unity of Odd Fellows; and then, on the fair assumption that the rates of sickness of the whole population during the working years of life would not be far different, he has calculated tables, showing the average annual rates of sickness of each person, enumerated in the Census of 1881 as living between the ages of fifteen and forty-five.

Briefly, it appears from these tables that the average time of sickness among males during the working years is 1·314 weeks—that is, a small fraction more than nine days each—in each year, and that among females it is yet a small fraction more. The result is that, among males, there is a loss of 9,692,505 weeks' work in every year, and among females a loss of 10,592,761 weeks. Thus we may believe that our whole population between fifteen and sixty-five years old do, in each year, 20,000,000 weeks' work less than they might do if it were not for sickness. The estimate is so large that it must, on first thoughts, seem improbable; but, on fair consideration, I believe it will not seem so. For the members of the Manchester Unity, who are in the working time of life, the reckoning is certainly true, and it is founded on the experience of between 300,000 and 400,000 members. In respect of health, they may represent the whole population at least as well as any group that could be taken. They are not very strictly selected; they are not picked lives; yet they are such as are able, when they are in health, to earn good wages or good salaries; and, as their prudence in joining this association shows, they are comparatively thrifty and careful persons. They do not, at all events, include many of the habitual drunkards, the cripples, or utterly invalids, or those who, through natural feebleness, or early disease, or mere profligacy, cannot earn enough to become members or maintain themselves in membership. Neither do they include many of the insane, or imbecile and idiotic, of whom there are in our population, nearly 70,000 doing no work, and losing not less than 3½ millions of weeks' work in the year.

It would be tedious to tell the grounds on which the estimate may be deemed too high, for just as many and as good could be told on which it might be deemed too low; and it is rather more than confirmed by some estimates of the annual sickness in other and very different groups of persons.

In the Army, at home, the average number of days' sickness in each year is, for each soldier, about seventeen; and, as the number of the troops in the United Kingdom is more than 80,000, we have here a loss of about 200,000 weeks' service in each year.

In the Navy, on the home stations, the average number of days' sickness in each year has been, in the last five years, for each man, nearly sixteen; so that, for the total of about 20,000 men, there is a loss of 45,000 weeks' service in each year.

The amount of sickness in the services thus appears much higher than in the Friendly Societies. This is due, in great part, to the fact that a soldier or a sailor is often put off duty for a day or two for much less illness than that for which a civilian would "go on his club." Still, the one estimate may confirm the other; for the sickness in the Army and Navy is that of picked men, who were selected for the services as being of sound constitution, and who are in what should be the best working years of life; and, if it includes many cases of sickness for only a day or two, it excludes nearly all cases of more than a few months, such as make up a heavy proportion of the average sickness in the Friendly Societies and in the general population. And I may add that the estimates from these societies, that nine days in the year may justly be thought a fair estimate of the working time lost by sickness, is confirmed by the records of sickness among the 10,000 members of the Metropolitan Police Force; for among these, including cases of long illness, such as are also in the societies, the average is more than nine days in the year.

I think, then, that we cannot escape from the reasons to believe that we lose in England and Wales, every year, in consequence of sickness, 20,000,000 of weeks' work; or, say, as much work as 20,000,000 of healthy people would do in a week.

The number is not easily grasped by the mind. It is equal to about one-fortieth part of the work done in each year by the whole population between fifteen and sixty-five years old. Or, try to think of it in money. Rather more than half of it is lost by those whom the Registrar-General names the domestic, the agricultural, and the industrial classes. These are rather more than seven millions and a half in number, and they lose about 11,000,000 of weeks; say, for easy reckoning, at a pound a week; and here is a loss of £11,000,000 sterling from what should be the annual wealth of the country. For the other classes, who are estimated as losing the other 9,000,000 weeks' work, it would be hard and unfair to make a guess in any known coin; for these include our great merchants, our judges and lawyers and medical men, our statesmen and chief legislators; they include our poets and writers of all kinds, musicians, painters, and philosophers; and our princes, who certainly do more for the wealth and welfare of the country than can be told in money.

Before I speak of any other losses of work or of wealth due to sickness, permit me, as in parenthesis, to point out to you how very imperfectly these losses are told or even suggested by our bills of mortality. These, on which almost alone we have to rely for knowing the national health—these tell the losses of life; and more than misery enough they tell of; but to estimate rightly the misery of sickness and the losses of all but life that are due to it, we need a far more complete record than these can give.

Take, for example, such a disease as typhoid fever—that which Mr. Huxley has rightly called the scourge and the disgrace of our country. It has of late destroyed in England and Wales, among persons in the working time of life, nearly 4000 in the year. Its mortality is about 15 per cent.; so that if, in any year, 4000 die of it, about 23,000 recover from it. Of these the average length of illness is, on the authority of Dr. Broadbent, about ten weeks. Here, therefore, from one disease alone, and that preventable, we have an annual loss of 230,000 weeks' work, without reckoning what is lost with those who die. And the same may be said of nearly all the diseases that are most prominent in the bills of mortality. The record of deaths, sad as it is, tells but a small part of the losses of happiness and welfare that are due to sickness. It is as if, in a great war, we should have a regular return of the numbers killed, but none of the numbers wounded, though these, more than the killed, may determine the issue of the war.

Let me now tell of another loss of work and of money through sickness and early death. In all the estimates I have yet referred to, no account is taken of those who are ill, or die, before they are fifteen years old. They are not reckoned as in the working time of life, though in some classes many thousands of them are; in the domestic, agricultural and industrial classes of the Registrar-General, nearly half a million of them are included, and yet the losses of work due to sickness among children must be very large. Consider the time which might be spent in good productive work, if it were not spent in taking care of them while they are ill. Consider, too, the number of those who, through disease in childhood, are made more susceptible of disease in later life, or are crippled, or in some way permanently damaged; such as those who become deaf in scarlet fever, or deformed in scrofula or rickets, or feeble and constantly invalid, so that they are never fit for more than half work, or for work which is only half well done. These losses cannot be counted, but they must be large, and there are others more nearly within reckoning—the losses, namely, which are due to the deaths of those who die young. It may justly be said that all that they have cost during their lives is so much money sunk, so much capital invested and lost. If they had lived to work their earnings would have been more than sufficient to repay it; but they have died, and their cost is gone without return. The mortality of children under fifteen in 1882, was nearly a quarter of a million. What have they cost? If you say only £8 a piece, there are more than £2,000,000 sterling thus lost every year. But they have cost much more than this, and much more still is lost by the loss of the work they might have lived to do.

It is, indeed, held, I believe, by some that these things should not be counted as losses; that we have a surplus of population, and that really the deaths of children, though they may be the subjects of a sentimental sorrow, cannot reasonably be regretted. I cannot bring myself to admit that such a thing should even be argued. I have lived long in the work of a profession which holds that wherever there is human life it must be preserved—made happy, if that can be, but in any case, if possible, preserved—and no argument of expediency shall ever make me believe that this is wrong. Indeed, I am rather ashamed—even for the purpose that I have in view—to use so low an argument as that of expediency in favour of the saving of health and of life. I am ashamed of making money appear as a motive for doing things for which sufficient motives might be found in charity and sympathy, and the happiness of using useful knowledge; but it seems certain that these are not yet enough for all that should be done for the promotion of the national health; therefore it seems well to add to them any motives that are not dishonourable; and so I add this, that we lose largely, not only in happiness, but in wealth, by the deaths of these poor children.

I will add only one more illustration of these losses, which is always suggested by looking at tables of mortality. The deaths of persons between twenty-five and forty-five years old, that is, during what may be deemed the twenty best working years of life, are annually between 60,000 and 70,000; in 1882 they were 66,000. Think, now, of the work lost by these deaths; and of how much of it might have been saved by better sanitary provisions. If one looks at the causes of their deaths it is certain that many might have been prevented, or, at least, deferred. Say that they might have lived an average of two years more, and we should have had in this year and last an increase of work equivalent to that of, at least, 6,000,000 weeks; as much, in other words, as 6,000,000 people could do in one week.

More instances of losses of work by sickness and premature death might easily be given, but not easily listened to in this huge hall. Let these suffice to show something of our enormous annual loss, not only of personal and domestic happiness—that is past imagining—but of national power and wealth. Surely we ought to strive more against it.

But, some may ask, can these things be prevented? Are they not inevitable consequences of the manner of life in which we choose or are compelled to live? No; certainly they are not. No one who lives among the sick can doubt that a very large proportion of the sickness and the loss of work which he sees might have been prevented; or can doubt that, in every succeeding generation, a larger proportion still may be averted, if only men will strive that it may be so.

Let me enumerate some of the chief sources of the waste, as they appear to oneself in practice.

Of the infectious fevers, small-pox might be rendered nearly harmless by complete and careful vaccination. Typhus and typhoid, scarlet fever and measles, might, with proper guards against infection, be confined within very narrow limits. So, probably, might whooping-cough and diphtheria.

Of the special diseases of artizans there are very few of which the causes might not be almost wholly set aside. Of the accidents to which they are especially liable, the greater part, by far, are due to carelessness.

Of the diseases due to bad food and mere filth; to intemperance; to immorality; in so far as these are self-induced, they might, by self-control and virtue, be excluded. And with these, scrofula, rickets, scurvy, and all the wide-spread defects related to them, might be greatly diminished.

It can only be a guess—but I am sure it is not a reckless one—if I say, that of all the losses of work of which I have spoken, of all the millions of weeks sadly spent and sadly wasted, a fourth part might have been saved, and that henceforth, if people will have it so, a still larger proportion may be saved.

We may become the more sure of what may be done by looking at what has been done already. Let me show some of it; it will be a relief to see something of the brighter side of this picture.

In a remarkable paper lately read before the Statistical

Society, Dr. Longstaff says:—"One of the most striking facts of the day, from the statistician's point of view, is the remarkably low death-rate that has prevailed in this country during the last eight years." In these years, the annual death-rate has been less than in the previous eight years in the proportion of two deaths to every 1000 persons living. The average number of deaths has been 50,000 less in the last than in the previous eight years. Doubtless many things have contributed to this grand result, and it is not possible to say how much is due to each of them; but it would be unreasonable to doubt that the chief good influence has been in all the improved means for the care of health which recent years have produced. This is made nearly certain by the fact that the largest gains of life have been in the diminution of the deaths from fever, and of the deaths in children under fifteen years old; for these are the very classes on which good sanitary measures would have most influence.

The annual number of deaths from typhus, typhoid, and the unnamed fevers, has been about 11,000 less than it was about twenty years ago. The annual number of deaths of children under five years old has been about 22,000 less than it was; and that of children between five and fifteen has been upwards of 8000 less.

These are large results, and though they tell of only deaths, yet they bear on the chief subject I have brought before you—the working power of the nation; for, however much we might assign to improved methods of medical treatment of fever, yet the diminished number of deaths means a very large diminution in the total number of cases. The deaths during the working years of life were 6500 less; and, this being so, we may hold that, if the average mortality was, say, 25 per cent., the diminution in the total number of cases must have been at least 25,000; and if we may believe, as before, that each of these involved ten weeks of sickness, we have, in these fevers alone, a clear saving of 185,000 weeks' work in every year.

And so, with the diminution of the mortality among children, there must have been a greater diminution in the number of costly and work-wasting illnesses, and a large saving of money that would otherwise have been sunk. And not only so, but many of the children saved in the last eight years will become bread-winners or care-keepers; and who can tell what some of them will become? or what the world would have lost if it had lost them?

Let me add only one more reckoning. In a paper last year, at the Statistical Society, Mr. Noel Humphreys said "that if the English death-rate should continue at the low average of the five years 1876–80, the mean duration of male life in this country would be increased by two years, and that of female life by no less than 3·4 years, as compared with the English life-table." And he showed further that, "among males, 70 per cent., and among females, 65 per cent., of this increased life would be lived between the ages of twenty and sixty years, or during the most useful period."

I should like to be able to tell the value in working power of such an addition to our lives. It is equal to an addition of more than 4 per cent. to the annual value of all the industry, mental and material, of the country.

But, some will say, admitting that it is desirable, though seeing how keen the struggle for maintenance already is, can more than this be done? and the answer may be and must be, much more. In this, as in every case of the kind, every fruit of knowledge brings us within reach of something more. While men are exercising the knowledge they possess, they may be always gaining better. This Exhibition has scores of things which are better helps to national health than those of the same kind which we had twenty years ago, and with which the gains already made were won. If I were not in near official relation with the jurors, I would name some of them; there are truly splendid works among them.

But do not let me seem to disparage the past in praising the present. It is difficult to speak with gratitude enough of what has been done, even though we may now see ways to the yet better.

Anyone who has studied the sources of disease during the last thirty years can tell how and where it has been diminished. There is less from intemperance, less from immorality; we have better, cheaper, and more various food; far more and cheaper clothing; far more and healthier recreations. We have, on the whole, better houses and better drains; better water and air, and better ways of using them. The care and skill with which the sick are treated in hospitals, infirmaries, and even private houses, are far greater than they were; the improvement and extension of nursing are more than can be described; the care which the rich bestow on the poor whom they visit in their own homes, is every day saving health and life; and even more effectual than any of these is the work done by the medical officers of health and all the sanitary authorities now active and influential in every part of the kingdom.

But good as all this work has been, we may be sure it may become better. The forces which have impelled it may still be relied on. We need not fear that charity will become cool, or philanthropy inactive, or that the hatred of evil will become indifference. Science will not cease to search for knowledge, or to make it useful when she can; we shall not see less than we do now, and here, of the good results of enterprise and rivalry, or of the sense of duty, or of the sorrow for shame that there should be these evils in the land.

What more, then, it may be asked, is wanted? I answer, that which I have tried to stir; a larger and more practical recognition of the value and happiness of good national health; a wider study and practice of all the methods of promoting it; or, at least, a more ready and liberal help to those who are striving to promote it. In one sentence, we want the complete fulfilment of the design of this Exhibition, with all the means towards health and knowledge that are shown in it, and with its hand-books, lectures, conferences, and the guidance which will be given by the verdicts of its juries.

We want more ambition for renown in health. I should like to see a personal ambition for renown in health as keen as is that for bravery, or for beauty, or for success in our athletic games and field-sports. I wish there were such an ambition for the most perfect national health as there is for national renown in war, or in art, or commerce. And let me end soon by briefly saying what I think such health should be.

I spoke of the pattern healthy man as one who can do his work vigorously wherever and whatever it may be. The union of strength with a comparative indifference to the external conditions of life, and a ready self-adjustment to their changes, is a distinctive characteristic of the best health. He should not be deemed thoroughly healthy who is made better or worse, more or less fit for work, by every change of weather or of food; nor he who, in order that he may do his work, is bound to exact rules of living. It is good to observe rules, and to many they are absolutely necessary; but it is better to need very few besides those of moderation and cleanliness, and, observing these, to be able and willing to live and work hard in the widest variations of food, air, clothing, and all the other sustenances of life.

And this, which is a sign of the best personal health, is essential to the best national health. For in a great nation, distributed among its people, there should be powers suited to the greatest possible variety of work. No form or depth of knowledge should be beyond the attainment of some among them: no art should be beyond its reach; it should be excellent in every form of work. And, that its various powers may have free exercise and influence in the world, it must have, besides, distributed among its people, abilities to live healthily wherever work must be or can be done.

Herein is the essential bond between health and education; herein is one of the motives for the combination of the two within the purpose of this one Exhibition. I do not know whether health or knowledge contributes most to the prosperity of a nation; but no nation can prosper which does not equally promote both; they should be deemed twin forces, for either of them without the other has only half the power for good that it should have.

It is said, whether as fact or fable, that the pursuit of science and of all the higher learning followed on the first exercise of the humanity which spared the lives of sick and weakly children; for that these children being allowed to live, though unfit for war or self-maintenance, became thinkers and inventors. But science and art are not dependent upon invalids; minds are not the more free or the better now for having to work in feeble bodies; each nation needs for its full international influence both health and knowledge, and such various and variable health, that there should be few places on earth or water in which some of its people cannot live, and multiply, and be prosperous.

If, therefore, we or any other people are to continue, ambitious for the extension of that higher mental power of which we boast, or for the success of the bold spirit of enterprise with which we seek to replenish the earth and subdue it; if we desire that the lessons of Christianity and of true civilization should be spread over the world, we must strive for an abundance of this national health, tough, pliant, and elastic, ready and fit for any good work anywhere.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual general meeting of the above Association was held at 53, Conduit Street, on May 14.

The report of the past session was read and adopted. It stated that the Association then numbered ten honorary, and sixty-one ordinary members, twelve new members having been enrolled during the session. Twenty-three meetings had been held during the past session, including five social and musical evenings. The largest attendances had been 31, 31, 30, 28 and 24, the aggregate 417, showing an average of 18. Sixteen papers on different subjects had been read, notices of which have from time to time already appeared in this Journal. The social evenings had continued to be a marked success. The annual dinner, held as usual at the Holborn Restaurant, under the presidency of Mr. S. R. Atkins, had been very largely attended. The Council, in the hope of increasing the usefulness of the Association, and augmenting the advantage of membership, had, during the past session, subscribed to Mudie's library, and subject to certain rules, had supplied all kinds of books obtainable from that library, other than works of fiction. In conclusion the Council expressed its gratitude to the authors of papers, to donors to the funds of the Association, and to the large body of the trade generally, who had shown their kindly feeling towards and interest in the Association.

The report having been read, the following gentlemen were elected members of the Council for the esuing session:—Messrs. Parkinson, Hadfield, Winfrey, Millhouse, Braithwaite, Williams, Cracknell, Burnett, Dodd, Cunningham, Baily, Flintan, Perkins and Flint.

The balance sheet for the past year was then accepted, and the meeting adjourned.

CONFERENCE OF INSPECTORS OF WEIGHTS AND MEASURES.

The annual conference of the British Association of Inspectors of Weights and Measures was opened at Glasgow on Tuesday morning, the members assembling in one of the halls in the Christian Institute. There was a numerous and representative attendance. Bailie Fullerton, of Greenock, was called upon to preside over the opening proceedings.

The Chairman said this was the first occasion on which the Association had met in Glasgow, and he believed that the interests which it sought to advance could not fail to recommend it to the general public of the West of Scotland. A desire to see the national system of weights and measures brought to a high state of perfection, and an anxiety to promote the enactment of such imperial statutes or corporation bye-laws as were most likely to secure just dealing, and leave no loophole for fraud, was surely a laudable ambition for this or any other society to have in view. At last year's meeting at Sheffield some time was occupied in discussing the Weights and Measures Act of 1878, and a number of suggestions of a valuable nature were discussed and submitted for the consideration of the Board of Trade. He trusted that the outcome of the deliberations during the present meeting of the Association would tend to the rectification of any abuses in connection with the Weights and Measures Act, and lead to improved legislation on the question, and that the proceedings would meet with the approbation of the country at large.

The report of the Committee, read by the Secretary, stated that the past year had not furnished anything very striking with regard to weights and measures. It must be apparent to anyone who had any experience of the working of the Weights and Measures Act how few local authorities attached that importance to it which the matter deserved; and unfortunately what was true of the local authorities was to a certain extent true of many inspectors. With a view of trying to create a more lively and genuine interest in the question of weights and measures, the Committee had issued information on the subject to others than members of the Association, in the hope that the seed thus sown might bear fruit at no very distant day. During the year the Committee, it was reported, had forwarded resolutions to the Board of Trade against legalizing a new standard weight of 112 lb., and in favour of the inspection of Post Office scales and weights by duly authorized inspectors. The membership at present was as follows:—30 ordinary, 18 extraordinary and 11 honorary members; or a total of 59, against 53 last year.

Mr. W. H. Hopkins, Treasurer, submitted the financial statement of the Association's position. The income was stated at £76 0*s*. 9*d*., and after meeting the expenditure a balance of £30 8*s*. remained, that sum being £3 4*s*. 9*d*. less than the sum the Association began the previous year with. This, it was explained, was only an apparent falling off, as subscriptions to the amount of £30 were still to be paid.

Mr. J. Hare, Birmingham, moved that Leeds be the next place of meeting. He had been desirous that London should have been chosen rather—they had many prejudices to attack there at headquarters—but Leeds was a place of very great importance.

Mr. Shaw, Edinburgh, seconded the proposal, and it was unanimously adopted.

Mr .William Scott Brown (Manchester) was then re-elected President for the ensuing year. Alderman Chunley was re-elected Vice-President, and the Treasurer, Secretary, Committee and Auditors were afterwards appointed

Opposition to the Proposed 112 *lbs. Weight.*

Mr. Walker (Glasgow) laid before the Association a motion to the effect that the members of the British Association of Inspectors of Weights and Measures respectfully submit to the Board of Trade that they do not consider it at all necessary, and certainly not desirable, that a new standard weight of 112 lbs. should be legalized, and for the reasons that it was so near in size to the cental or 100 lbs. weight, and in consequence liable to be used fraudulently; that anyone requiring such a large weight could use the already legalized cental; that if a concession was to be made to one business the Board of Trade could not consistently refuse to grant a special weight to any other business; and that the concessions asked for by the ironmasters, if granted, would destroy the main principle of the Weights and Measures Act, 1878. Mr. Walker's chief objection to the new weight was the increase of the already large number of standard weights—ninety-four being at present in use.

Mr. A. Pickering seconded the motion, and others having spoken in its favour, it was adopted.

The Inspection of Post Office Scales.

Mr. Wimhurst moved that, in the opinion of the meeting, it was not only desirable, but absolutely necessary for the protection of the public, that duly authorized inspectors of weights and measures should be empowered to enter any place where weights and scales were kept and used by the *employés* of the Post Office. Mr. Wimhurst referred to the action of the Post Office authorities in Manchester in securing exemption from inspection by the inspectors of weights and measures. He trusted that the result of the correspondence that had taken place between the Board of Trade and the Post Office would be that the inspectors of weights and measures would be allowed to go into post offices, so that the public would have confidence in these scales.

Mr. Walker seconded the motion, which was ultimately adopted.

Illegal Weights in Government Offices.

Mr. Pickering (Sunderland) proposed that the meeting should call the attention of the Board of Trade to the continued use of the old troy weights in some districts and in Government offices—the latter fact being given as a reason by a magistrate who dismissed a summons for the use of such—and the stamping of new weights of such denominations, which is clearly illegal.

Mr. Walker seconded, and the resolution was agreed to.

Inspectors' Fees.

Mr. Shaw submitted a motion that pleaded for an amendment of the Weights and Measures Act of 1878, to secure compulsory uniformity of fees for the verification and stamping of weights and measures established throughout the United Kingdom, and that legislation should be passed to that effect without unncessary delay. The motion also proposed that a committee of the Association be appointed to present to the Board of Trade a memorial embodying the resolution, and with powers to take all necessary steps to secure an early accomplishment of the object in view.

Mr. Walker seconded the motion, and it was adopted.

The Vagaries of Weights Makers.

Mr. Pickering moved that, in the opinion of the Association, it is highly desirable, for several reasons, that the vagaries which distinguish the manufacture and stamping of ordinary commercial weights should in future be avoided; and that the inspectors, anxious to make progress in this direction, request the Honorary Secretary to address to the manufacturers a friendly communication, asking them to take such steps, either in concert or otherwise, as will give uniformity in the style of stamping the denomination on weights, particularly brass weights, so that adequate room may be left for the stamp of verification, and a greater measure of regularity, neatness and efficiency attained.

Mr. J. Parnall (Bristol) seconded the motion, and it was adopted.

Afternoon Sitting.

At the afternoon sitting Mr. W. H. Hopkins, of Manchester, took the chair at the commencement of the proceedings.

Mr. W. Shaw, of Edinburgh, read a paper entitled "Observations on the Weights and Measures of Apothecaries, and the necessity existing for exactness in comparing and verifying the same." After alluding to the weights and measures in general use for many years, for dispensing medicines, until the new series were legalized in 1879, he spoke at some length upon the suspicious way in which the drug trade looked upon inspectors. Suggestions that had been made by the Board of Trade had turned out to be of no use, as the inspectors had no power to enforce them. At length, in 1880, standards were got, and three months' time was given before any visits were made. No undue haste was shown. however, in carrying out the new regulations. Although about eighteen months were allowed to elapse before he made any visits, he found large numbers of the weights in use in Edinburgh incorrect, some being too heavy and others too light. Some of them were dangerously wrong for dispensing certain kinds of medicines. Measures and balances were also found to be wrong. It was clearly the duty of the inspectors to see that such shops in their districts were visited—not in a persecuting spirit, but to make sure that things were being kept all right.

Mr. Wimhurst read a paper on the 24th, 25th and 29th sections of the Weights and Measures Act, 1878, and the 8th section of the Licensing Act, 1872. He alluded to the use of glass measures by licensed traders, which in several districts had been examined, and orders given to have them sent in and stamped. In one or two towns no action had been taken with regard to glasses marked half-pints, but he thought that inspectors should deal with all kinds of glass measures. It was perhaps not so easy to make a correct glass measure as a pewter one, but since attention had been given to this subject it was astonishing to find the improvement that had taken place in their manufacture. It was distinctly stated in the Act that all quantities of liquids asked for over half a pint should be served in a glass vessel. When customers did not ask for the liquor according to imperial measure they were liable to to be served with smaller quantities. Any glass measure could be made quite accurate by making it a little larger than at present, and putting a line round the rim to indicate how far it should be filled up to give the exact quantity marked upon it. He thought that powers should be given to inspectors to make purchases, and prosecute if the correct quantity was not supplied.

Mr. Richmond referred to a recent prosecution in Glasgow, which went to the Court of Session, when Lord Young dismissed the case, saying that the measures taken away were "local and customary ones,' if not recognized in the Board of Trade list or stamped.

Mr. Walker (Glasgow) explained that the measures complained of, not being imperial ones, could not be verified by the inspector. The attention of the shopkeeper who was using them was called to the circumstance, and he was requested to cease using them, but declined to do so. The measures were then seized and a prosecution raised, but, while the local magistrate convicted, Lord Young dismissed the case, chiefly on account, it was believed, of the way in which the prosecution was conducted.

The Dinner.

In the evening the members of the Association and their friends dined together in Macgregor's Hotel.

Parliamentary and Law Proceedings.

New York State Pharmacy Law.

An Act to establish a Board of Pharmacy and to regulate the practice of pharmacy for all the counties of New York State except New York, Erie, and Kings.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:—

Section 1. There shall be established and created a Board of Pharmacy as follows:

1. Within ninety days after the passage of this Act the New York State Pharmaceutical Association shall

nominate ten pharmacists, residents of the district to which this Act applies, from which number the Governor of the State shall, within twenty days after notice to him of such nomination, appoint five, who shall constitute the Board of Pharmacy.

2. It shall be the duty of each member of the Board of Pharmacy, immediately after the receipt of the notice of his appointment, to appear before the clerk of the county in which he resides, and make and subscribe an oath to properly and faithfully discharge the duties of a member of the said Board of Pharmacy.

3. One of said members shall hold office for one year, one for two years, one for three years, one for four years, and one for five years from the first Tuesday of September, in the year one thousand eight hundred and eighty-four, which term shall be determined by lot at the first meeting of said Board of Pharmacy.

4. The said members of said Board shall meet on the first Tuesday of September, in the year one thousand eight hundred and eighty-four, at the College of Pharmacy building, in the city of Albany at twelve o'clock, noon, of that day, and shall immediately proceed to organize by determining by lot the respective terms for which they shall hold office, and by electing a President, Treasurer, and Secretary, who shall hold their respective offices for the term of one year.

5. The Board shall hold meetings at least once in three months. Three members shall constitute a quorum.

6. The said Board shall have power to make such bye-laws, not inconsistent with the constitution, or the provisions of this Act, as it may deem necessary.

Section 2. It shall be the duty of the Board of Pharmacy—

1. To examine all persons applying for licences under this Act, and to grant licences to such persons as may be entitled to the same.

2. To keep a record of licensed pharmacists.

3. To investigate all complaints of disregard, non-compliance, or violation of the provisions of this Act, and to bring all cases of violation to the notice of the proper prosecuting officers.

Section 3. Any person who at the time of the passage of this Act is carrying on the business of retailing or dispensing drugs, medicines, or poisons, or practising pharmacy on his own account, or who, at the time of the passage of this Act, shall have served five years or upwards at the business of retailing or dispensing drugs, medicines, or poisons or practising pharmacy, and who is over the age of twenty-one years, or any person who holds a certificate of registration as a pharmacist from any Board of Pharmacy legally created under the laws of this State, or any person who holds a diploma as a graduate of any incorporated college of pharmacy of this State, shall be granted a licence by said Board of Pharmacy to practise as a pharmacist upon compliance with the requirements hereinafter stated.

Section 4. Any person entitled to a licence as a pharmacist, as provided for in section 3, who shall not, within ninety days after the organization of the Board of Pharmacy, as herein provided, make a written application to such Board for such licence, accompanied by a written statement signed by him or her and duly verified before an officer authorized to administer oaths within this State, fully setting forth the grounds upon which he or she claims such licence, shall be deemed to have waived his or her right to a licence under the provisions of said section.

Section 5. No licence shall be granted to any person under the provisions of section 3 of this Act unless the applicant pays to said Board of Pharmacy the sum of five dollars.

Section 6. The said Board of Pharmacy shall make such regulations for the examination of applicants for licences and the granting of licences to such applicants and the payment of licence fees as it may deem proper, but no licence fee shall exceed the sum of five dollars.

Section 7. The New York State Pharmaceutical Association shall, annually, after the first Monday in June, in the year eighteen hundred and eighty-four, nominate ten pharmacists, residents of the district to which the Act applies, from which number the Governor shall fill the vacancy annually occurring in the Board, and the person so appointed by the Governor shall hold office for five years. In case of the death, resignation, or removal from the State of any member of the Board before the expiration of his term of office, or in case of vacancy occurring from any other cause but expiration of term of office, the Governor shall fill the vacancy from the list of names nominated as aforesaid during the year in which such vacancy occurs, and the person appointed shall hold for the unexpired term of his predecessor.

Section 8. Every person to whom a licence is granted by said Board of Pharmacy shall display the same in a conspicuous part of the pharmacy in which he or she does business.

Section 9. No licence granted by said Board of Pharmacy shall be revoked except for just and sufficient cause.

Section 10. It shall be unlawful, after the first day of January, in the year one thousand eight hundred and eighty-five, for any person to practise as a pharmacist unless he or she shall have been granted a licence by said Board.

Section 11. Nothing in this Act shall be so construed as to apply to the business of a practitioner of medicine, nor to prevent practitioners of medicine from supplying their patients with such articles as they may deem proper; nor to those who sell medicines and poisons at wholesale; nor to the manufacture or sale of patent or proprietary medicines; nor to the sale of the usual domestic remedies by retail dealers in the rural districts. And nothing in this Act shall be so construed as to prohibit the employment in any pharmacy of apprentices or assistants, for the purpose of being instructed in the practice of pharmacy: but such apprentices or assistants shall not be permitted to prepare and dispense physicians' prescriptions, or to sell or furnish medicines or poisons except in the presence of and under the personal supervision of a licensed pharmacist.

Section 12. All violations of the provisions of this Act shall be deemed misdemeanours and shall be punished as such.

Section 13. This Act shall not apply to the counties of New York, Erie, and Kings.

Section 14. All Acts and parts of Acts inconsistent with the provisions of this Act are hereby repealed.

Section 15. This Act shall take effect immediately.

ANSWERS TO CORRESPONDENTS.

R. H. Burchell.—"Methylated finish" is exempt from payment of duty. But it must contain at least three ounces of shellac, seedlac, sandrac, or colophony dissolved in every gallon; otherwise it can only be sold under licence as methylated spirit.

T. R. D.—The right to use the term "pharmaceutical chemist" is not transferable from one person to another.

J. B.—For a recipe for india rubber cement, see before, p. 600.

E. J. H.—(1) The question has not yet been legally decided. (2) The seller of such a wine would require to hold a wine licence, unless by the manner in which it was advertised it was brought within the scope of the Patent Medicines Act.

D. P.—The Syrupus Ipecacuanhæ, P.G., the formula for which is—Bruised ipecacuanha root, 1 part; macerate for twenty-four hours in spirit (sp. gr. 0·892) 5 parts and water, 40 parts; filter 40 parts and add sugar, 60 parts, to make a syrup and filter cold. All parts by weight.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Wilkinson, Kinninmont, Hutchinson, MacEwan.

INDEX TO VOL. XIV.

(THIRD SERIES.)
